Lecture No 32
Numerical Integration Part II

Welcome to the lecture series on numerical methods and in the last lecture we have discussed numerical integration. In the numerical integration we have started about this rectangular rule that how we can just implement to find this integration for a particular function. Even if this function is not known to us but the tabular values like functional values at different points if it is known to us then we can evaluate this integration by using this nodal or tabular values.

(Refer Slide Time: 00:57)

So this class we will just go for this some of this higher-order integration methods, so first will discuss about this Quadrature formula here, then we will just go for 2 point formula that is trapezoidal rule, then we will just go for this geometrical interpretation of this trapezoidal rule here and we will just go for error estimation in a trapezoidal rule, then for composite formula of trapezoidal rule. If the point is like in each of the intervals if you will just use 2 points then the total interval if you will just use this then basically that is called composite trapezoidal rule and how we can just obtain the formula that I will just discuss in this lecture.

(Refer Slide Time: 01:38)

Numerical Integration

Quadrature Formula

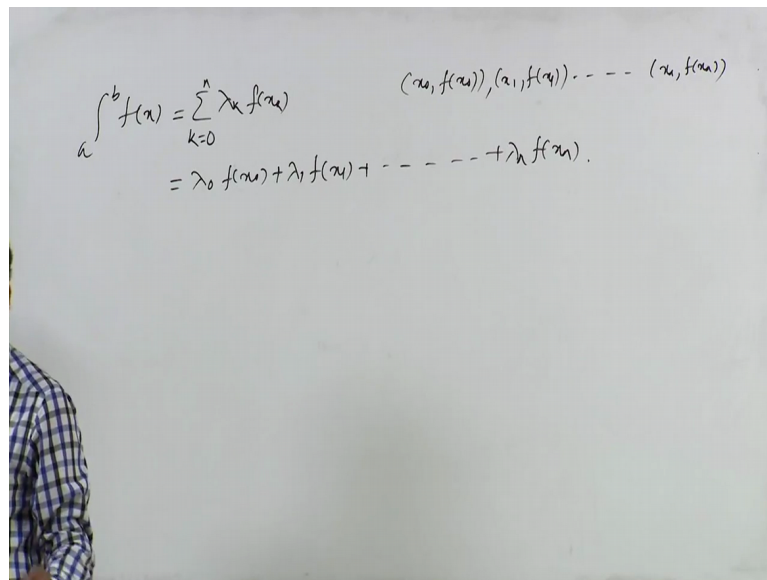

□ The integral is approximated by a linear combination of the values of $f(x)$ at tabular points as,

$$I = \int_a^b f(x) dx = \sum_{k=0}^n \lambda_k f(x_k)$$
$$= \lambda_0 f(x_0) + \lambda_1 f(x_1) + \lambda_2 f(x_2) + \dots + \lambda_n f(x_n) \quad \dots\dots\dots (1.1)$$

The tabulated points x_k 's are called abscissas, $f(x_k)$'s are called ordinates and λ_k 's are called weights. Expression (1.1) is called **quadrature formula**.

 IIT Kharagpur  NPTEL ONLINE CERTIFICATION COURSE

3

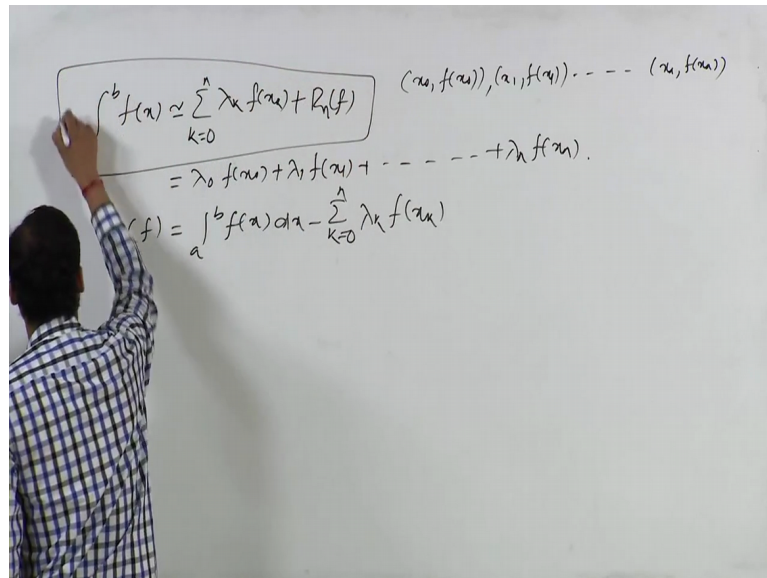

$$\int_a^b f(x) dx = \sum_{k=0}^n \lambda_k f(x_k)$$
$$(x_0, f(x_0)), (x_1, f(x_1)), \dots, (x_n, f(x_n))$$
$$= \lambda_0 f(x_0) + \lambda_1 f(x_1) + \dots + \lambda_n f(x_n)$$

So first if you just go for this Quadrature form here usually this integral is approximated by linear combination of this functional values of f of x at tabular points. This means that integration a to b , f of x into dx it can be expressed in the form of summation k equals to 0 to n , $\lambda_k f(x_k)$ here. Since already it is known that unless always we will have this set of tabular values that is in the form of like $x_0, f(x_0), x_1, f(x_1)$ upto $x_n, f(x_n)$ here. So if this set of tabular values is known to us then we can just implement this Quadrature formula basically evaluate this integration by using this tabular values here.

So especially if you will just expand this formula here that is the linear combination of this functional values are different tabular points then we can just write this one as $\lambda_0 f(x_0) + \lambda_1 f(x_1) + \dots + \lambda_n f(x_n)$ here. This tabulated point x_k 's are

called abscissas and f of x_k 's are called coordinates here or ordinate we can just say and λ_k 's are called weights for this function here or this integration here and this complete expression it is called Quadrature formula.

(Refer Slide Time: 03:22)

$$\int_a^b f(x) \approx \sum_{k=0}^n \lambda_k f(x_k) + R_n(f)$$

$$= \lambda_0 f(x_0) + \lambda_1 f(x_1) + \dots + \lambda_n f(x_n)$$

$$R_n(f) = \int_a^b f(x) dx - \sum_{k=0}^n \lambda_k f(x_k)$$

$(x_0, f(x_0)), (x_1, f(x_1)), \dots, (x_n, f(x_n))$

And if we will just go for this competition of this Quadrature formula here usually this error formula R_n of f can be written as integration a to b , f of x dx minus summation k equals to 0 to n λ_k , f of x_k here. So if we want to evaluate this error always we have to subtract both this terms since especially directly we can just write this is not exactly equals to this is approximation of this term here and we can just write this plus R_n of f as the total expression for this complete integration formula here. Then we can just write R_n of x or R_n of f this equals to integration of a to b , f of x dx minus summation k equals to 0 to n , λ_k , f of x_k .

(Refer Slide Time: 04:22)

Numerical Integration

Error of quadrature formula:

$$\text{Error, } R_n(f) = \int_a^b f(x) dx - \sum_{k=0}^n \lambda_k f(x_k) \quad \dots(1.2)$$

Order of a method:

An integration method of the form (1.1) is said to be of **order p**, if $R_n=0$, for all polynomials of degree less than or equal to p. i.e. it produces exact result for $f(x)=1, x, x^2, x^3, \dots, x^p$. This implies

$$R_n(x^m) = \int_a^b x^m dx - \sum_{k=0}^n \lambda_k x_k^m = 0, \text{ for } m=0,1,2,\dots,p \quad \dots(1.3)$$

 IIT BOMBAY
  NPTEL ONLINE CERTIFICATION COURSE

4

Obviously sometimes we are just approximating this formula like certain order of form here, order of a method we can justify. Suppose this function is exact, suppose some of this order of the polynomial here then we can just say that in integration method of the form like we have just express a to b, f of x this equals to summation of k equals to 0 to n, lambda k, f of x k plus R n f here, this can be of order p i R n equal R n of f equal to 0 for all polynomial's of degree less than or equal to p here.

(Refer Slide Time: 05:17)

$$\int_a^b f(x) = \sum_{k=0}^n \lambda_k f(x_k) + R_n(f)$$

$$= \lambda_0 f(x_0) + \lambda_1 f(x_1) + \dots + \lambda_n f(x_n)$$

$$R_n(f) = \int_a^b f(x) dx - \sum_{k=0}^n \lambda_k f(x_k)$$

$$R_n(x^m) = \int_a^b x^m dx - \sum_{k=0}^n \lambda_k x_k^m = 0 \text{ for } m=0,1,2,\dots,p$$

$1, x, x^2, \dots, x^p$

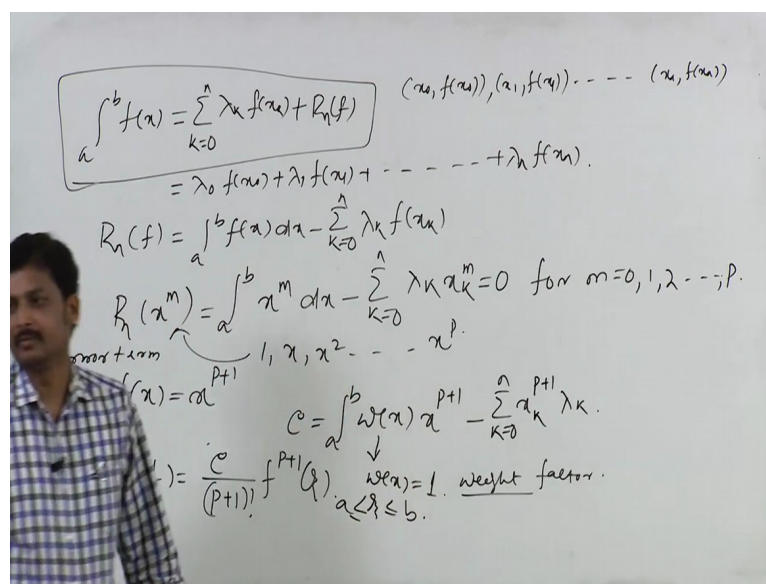

$(x_0, f(x_0)), (x_1, f(x_1)), \dots, (x_n, f(x_n))$

This means that it produces exact results for all polynomials that is in the form of f of x equals to 1, x, x square, upto x to the power p. This means we can just say that R n of x to the

power m this equals to integration a to b , x to the power m dx minus summation k equals to 0 to n , $\lambda_k x^k$ to the power m , this equals to 0 for m equals to $0, 1, 2$, upto p here.

So then we can just say that this integration method is said to be of order p here. Exactly if you just put here like $1, x, x$ square, upto x to the power p , exactly this value will just give you the 0 value there. So that is why it is said to be of order p here. And if you will just try to find out this error term here, if immediate next term if you will just consider then that will just provide the error term here.

(Refer Slide Time: 06:24)

Handwritten formulas on the whiteboard:

$$\int_a^b f(x) dx = \sum_{k=0}^n \lambda_k f(x_k) + R_n(f)$$

$$= \lambda_0 f(x_0) + \lambda_1 f(x_1) + \dots + \lambda_n f(x_n)$$

$$R_n(f) = \int_a^b f(x) dx - \sum_{k=0}^n \lambda_k f(x_k)$$

$$R_n(x^m) = \int_a^b x^m dx - \sum_{k=0}^n \lambda_k x_k^m = 0 \text{ for } m=0, 1, 2, \dots, p.$$

$x^m = x^{m+1} - x^m$

$$f(x) = x^{p+1}$$

$$C = \int_a^b \omega(x) x^{p+1} dx - \sum_{k=0}^n \lambda_k x_k^{p+1}$$

$$f(x) = \frac{C}{(p+1)!} f^{(p+1)}(\xi) \quad \omega(x) = 1 \text{ weight factor.}$$

$a \leq \xi \leq b$

So obviously we can just write the error term for f of x p here, f of x equals to x to the power of p plus 1 , this means that the error term for f of x is defined as we can just write C equals to integration a to b we can just write $\omega(x)$, x to the power p plus 1 minus summation k equals to 0 to n , x^k to the power p plus 1 , λ_k here, where C is called error constant and $\omega(x)$ especially always it is chosen as 1 this is called weights factor here. So that is why this formula can be written also directly as integration a to b , x to the power p plus 1 minus summation k equals to 0 to m , x^k to the power p plus 1 , λ_k here also.

(Refer Slide Time: 07:33)

The error term for $f(x) = x^{p+1}$ is defined as,

$$c = \int_a^b w(x) x^{p+1} dx - \sum_{k=0}^n \lambda_k x_k^{p+1}$$

where c is called the error constant.

Using (1.2) the error term takes the form :

$$R_n(f) = \int_a^b f(x) dx - \sum_{k=0}^n \lambda_k x_k^m$$

$$= \frac{c}{(p+1)!} f^{(p+1)}(\xi), \quad a < \xi < b \quad \dots(1.4)$$

The bound for the error term is given by,

$$|R_n(f)| \leq \frac{|c|}{(p+1)!} \max_{a \leq x \leq b} |f^{(p+1)}(x)| \quad \dots(1.5)$$

And if we will just calculate this total error term here, so if you will just use this integration formula directly we can just write that one as R_n of f this equals to integration or since we have already calculated the difference of this one this can be written as C by $p + 1$ factorial, f to the power $p + 1$ ζ here, where ζ should be lies between a and b here or you can just write R_n of f equal to integration a to b , f of x dx minus submission k equals to 0 to n , λ^k , x to the power x k to the power m this equals to C by $p + 1$ factorial, f to the power $p + 1$ ζ here, where ζ should be lies between 0 and 1 .

(Refer Slide Time: 08:34)

And if you want to find this bound for this error term here we can just find this absolute error term here this should be less or equal to absolute values of C by p plus 1 factorial and then immediate next term we can just find this into maximum of f to the power p plus 1, x for x lies between a to b here, this is completely defines the bound for the error term we can just define that one.

(Refer Slide Time: 09:16)

Numerical Integration

Integral Methods Based on Uniform Mesh Spacing:

For a prescribed data set with $x_0=a$, $x_n=b$ and $h=(b-a)/n$, the expression (1.2) takes the form:

$$I = \int_a^b f(x)dx = \sum_{k=0}^n \lambda_k f(x_k)$$

$$= \lambda_0 f(x_0) + \lambda_1 f(x_0+h) + \lambda_2 f(x_0+2h) + \dots + \lambda_n f(x_0+nh) \quad \dots(1.6)$$

The expression (1.6) is called *Newton-Cotes quadrature formula*.
The weights λ_n 's are called Cotes number.

6

So then we will just go for this integral methods based on uniform mesh spacing, suppose you will have this tabular points like x_0, x_1 to x_n here and all points are equi-spaced then how we can just evaluate this error using Quadrature formula that we will just discuss.

(Refer Slide Time: 09:40)

So if you will just go for this uniform mesh spacing here for a prescribe data set points like x_0 equals to a and x_n equals to b supposed then we can just define your space size that is h equals to b minus a by n , if we can just define this tabular values that is in the form of like x_0 this equals to a is less than x_1 , less than x_2 upto less than x_n equals to b and all these points are equi-spaced suppose x_0 , then x_1 , then x_2 upto x_n here, so all are equi-spaced here.

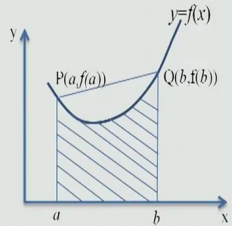

Then we can just write this integration i equals to integration a to b , f of x dx , this equals to summation k equals to 0 to n , λ_k , f of x_k here. Usually we can just write this one as λ_0 , f of x_0 , λ_1 , f of x_0 plus h , λ_2 , f of x_0 plus $2h$, upto λ_n , f of x_0 plus nh here And this expression specially are called Newton-Cotes Quadrature formula and λ_n 's are called Cotes number here, Cotes number and this formula is called Newton's cotes Quadrature formula.

(Refer Slide Time: 11:31)

Numerical Integration

Trapezoidal rule :

Let the curve $y=f(x)$, $a \leq x \leq b$ be approximated by a line joining the points P, Q on the curve (Fig 1.2).

Using the Newton's forward difference formula, the linear interpolating polynomial passing through $P(a, f(a))$ and $Q(b, f(b))$, is given by

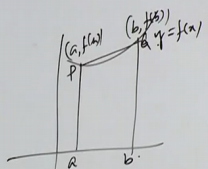

$$f(x) = f(x_0) + \frac{1}{h}(x-x_0)\Delta f(x_0) \quad \dots(1.7)$$

where $x_0=a$, $x_1=b$ and $h=b-a$.

Fig.1.2. Trapezoidal rule

7

$x_0=a, x_n=b, h=\frac{b-a}{n}$ if
 $a=x_0 < x_1 < x_2 < \dots < x_n=b$

$I = \int_a^b f(x) dx = \sum_{k=0}^{n-1} \lambda_k f(x_k)$
 $= \lambda_0 f(x_0) + \lambda_1 f(x_0+h) + \lambda_2 f(x_0+2h) + \dots + \lambda_n f(x_0+nh)$

λ_k 's are called Coefficients.
 $= f(x_0) + P \Delta f(x_0)$
 $= f(x) + \frac{x-x_0}{h} \Delta f(x)$

$x_0=a$
 $x_1=b$
 $h=b-a$

So first will just go for trapezoidal rule here, suppose we will have a curve here and it has this ordinates like a, f of a here and b, f of b here. So suppose this points are like p, q here, so if we want to find this area or this integration from a to b range with this function bounded by this curve y equals to f of x here then we can just estimate this area by a trapezium or trapezoid then we can just evaluate this integration in a complete form here.

Suppose this curve y equals to f of x is given to us and it is asked to find this integration within this range a to b suppose and this can be approximated by joining this line like p to q here in the curve and if you will just use this Newton's forward difference formula for a linear interpolating polynomial passing through this points like a, f of a and b, f of b here,

then since we are just approximating this curved region by straight line that, so that is why you can just approximate by a linear interpolating polynomial there.

So if you will just interpolate this linear interpolating polynomial for this curve here then we can just write this formula as f of x equals to f of x_0 plus p delta of f of x_0 here. Since it is a linear interpolating polynomial after that we can just get the 0 values, so that is why we can just write this terms upto this series here. And here in terms of x if you just express this expansion here, so this can be written as f of x_0 plus x minus x_0 by h , delta of f of x_0 , where we can just write x_0 equals to a here and x_1 equals to b here and your space size that is h can be defined as h equals to b minus a here.

(Refer Slide Time: 13:51)

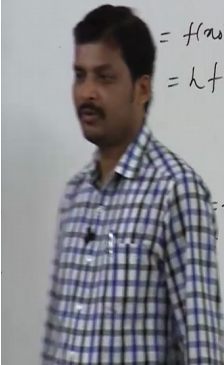

Numerical Integration

Substituting in (1.7) we obtain

$$\begin{aligned}
 I &= \int_a^b f(x) dx = \int_{x_0}^x f(x) dx \\
 &= f(x_0) \int_{x_0}^x dx + \frac{1}{h} \int_{x_0}^x (x - x_0) dx \Delta f_0 \\
 &= (x_1 - x_0) f(x_0) + \frac{1}{h} \left[\frac{1}{2} (x - x_0)^2 \right]_{x_0}^x \Delta f_0 \\
 &= (x_1 - x_0) f(x_0) + \frac{1}{2h} [f(x_1) - f(x_0)] (x_1 - x_0)^2 \\
 &= hf(x_0) + \frac{h}{2} [f(x_1) - f(x_0)] \\
 &= \frac{h}{2} [f(x_1) + f(x_0)] = \frac{(b-a)}{2} [f(b) + f(a)] \quad \dots(1.8)
 \end{aligned}$$

 NPTEL ONLINE CERTIFICATION COURSE

8

$$\begin{aligned}
 I &= \int_a^b f(x) dx = \int_a^{x_0} f(x_0) dx + \int_{x_0}^b f(x) dx \\
 &= \int_a^{x_0} f(x_0) dx + \int_{x_0}^b \frac{x - x_0}{h} [f(x_1) - f(x_0)] dx \\
 &= f(x_0) [x_1 - x_0] + \frac{f(x_1) - f(x_0)}{h} \left[\frac{(x - x_0)^2}{2} \right]_{x_0}^b \\
 &= hf(x_0) + \frac{f(x_1) - f(x_0)}{h} \cdot \frac{h^2}{2} = \frac{h}{2} [f(x_0) + f(x_1)] \\
 &= \frac{b-a}{2} [f(a) + f(b)] \\
 &= f(x_0) + p \Delta f(x_0) \\
 &= f(x_0) + \frac{x - x_0}{h} \Delta f(x_0)
 \end{aligned}$$

$x_0 = a$
 $x_1 = b$
 $h = b - a$

And then if you will just go for this integration of this function here over this range a to b , the integration from a to b , it can be written as integration a to b , f of x dx here and this can be written as integration a to b , f of x_0 dx plus integration a to b , p in terms of x if you just write this one so it can be written as x minus x_0 by h , Δf of x_0 dx here. And if you just replace this one in terms of x_0 and x_1 here, so this can be written as x_0 to x_1 , f of x_0 dx plus x_0 to x_1 , x minus x_0 by h , f of x_1 minus f of x_0 , d of x here.

And if you just integrate this one this can be written as like f of x_0 and x_1 minus x_0 plus this can be written as f of x_1 minus f of x_0 by h and next one it can be written as x minus x_0 whole square by 2 , x_0 to x_1 . And if you will just put here x_1 minus x_0 equals to h , this can be written as h , f of x_0 plus f of x_1 minus f of x_0 by h into h square by 2 . And finally if you will just write this can be written in the form of like h by 2 , f of x_0 plus f of x_1 here.

And that it can be represented also in the form of like h by 2 , f of a plus f of b if you will just replace here also h in terms of b and a , this can be written as, b minus a by 2 into f of a plus f of b here. So this is basically called 2 point Quadrature formula if you will just consider this linear interpolating polynomial which is interpolating this curve y equals to f of x in a particular region then we can just evaluate this integration here.

(Refer Slide Time: 16:25)

The trapezoidal rule is given by

$$\begin{aligned}
 I &= \int_a^b f(x) dx \\
 &= \frac{h}{2} [f(x_1) + f(x_0)] \\
 &= \frac{(b-a)}{2} [f(b) + f(a)] \quad \dots(1.9)
 \end{aligned}$$

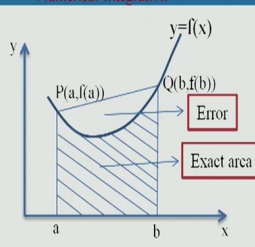

Fig.1.3

Geometrical interpretation:

Geometrically the trapezoidal rule (1.9) represents *the area of the trapezium with width $(b-a)$, and ordinates $f(a)$ and $f(b)$* , which is an approximation to the area under the curve $y=f(x)$ above the x -axis and the ordinates $x=a$ and $x=b$.

9

So next if you will just go for this geometrical interpretation that is we can just express this one that the area of trapezium if you will just see here with width b minus a and ordinates f of b and f of a , which is an approximate or which is an approximation to the area under the

curve y equals to f of x above the x -axis and the ordinates x equals to a and b , this is nothing but representing the area that is b minus a by 2 , f of a plus f of b .

(Refer Slide Time: 17:05)

So if we can just go for the geometrical calculation of this area here we can just say that we will have this 2 regions here that is a rectangular region if you will see this one and and this is a triangle region here also. So if you will just calculate the area for this rectangular here and the area of the this triangle in that region then also we can just get this total area under this 2 sections are as, b minus a by 2 into f of a plus f of b here.

So if you will just see here geometrically if you just calculate this area then the area bounded by this lines x equals to a , x equals to b , y equals to 0 and pq line that is area of the rectangular $APRB$ if you will just see plus area of the triangle PQR . So this is nothing but first this is total area of this rectangle we can just write b minus a into this height is f of a here, so that is why b minus a into f of a plus your triangular area that is half h into like b minus a . So usually we are just writing that is half into b minus a into f of b minus f of a here. So finally we can just get it as b minus a by 2 into f of a plus f of b here.

(Refer Slide Time: 18:28)

Numerical Integration

Error Estimate in Trapezoidal Rule:

It can be verified that the trapezium rule gives the exact value of the integration for polynomials of degree ≤ 1 . i.e. $R(f, x) = 0$ for $f(x) = 1, x$

For $f(x) = 1$: $R(f, x) = \int_a^b 1 dx - \frac{(b-a)}{2} 2 = (b-a) - (b-a) = 0$

For $f(x) = x$: $R(f, x) = \int_a^b x dx - \frac{(b-a)}{2} (b+a) = \frac{1}{2} (b^2 - a^2) - \frac{1}{2} (b^2 - a^2) = 0$

For $f(x) = x^2$: $c = \int_a^b x^2 dx - \frac{(b-a)}{2} (b^2 + a^2) = \frac{1}{3} (b-a)^3 - \frac{1}{2} (b^3 + a^2b - ab^2 - a^3)$

$$= \frac{1}{6} (a^3 - 3a^2b + 3ab^2 - b^3) = -\frac{1}{6} (b-a)^3$$

** The order of trapezoidal rule is 1 (one).*

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

So if you will just go for this error estimation for this trapezoidal rule, so we can just verify that this error as R of f, x equals to 0 for $f(x)$ equals to 1 and x . If already I have discussed that one, an integration method is said to be order p , if p is the largest positive real number for which the less numbers existing there that means 0, 1, 2 upto p all will give us the zero values there for the error term.

(Refer Slide Time: 19:05)

So then we can just express here for suppose f of x equals to 1 if you just consider then we can just express this one a to b , f of x dx minus our formula that is expressed as minus b minus a by 2, f of a plus f of b , or the value it is just providing that is nothing but the error

function here. So if you will just see here that is R of f of x here which can be written as like x 0 to x 1 or a to b whatever you want you can just write there. So that is if you just write a to b , 1 into dx minus b minus a by 2, since f of a is 1 here, f of b is 1 here, then we can just express this one as b minus a minus b minus a by 2 into 2 here, so this is just giving you 0 here.

Similarly, if will just go for f of x equals to x here then also we can just express a to b , x dx minus b minus a by 2 and f of x equals to x here, so f of a equals to a here and f of b is equal to b here. So then if you will just evaluate this one for R of f , x here this implies that this can be written in the form of x square by 2 minus this is a plus b into b minus a here, so b square minus a square by 2, this range is a to b here, this is nothing but R of f , x here, which can be written as 0 also for R of f , x here.

So if you will just consider like f of x equals to x square then we can just obtain the value for C here. This means that for f of x equals to x square since we have considered this polynomial of degree one here or we are just approximating this function with polynomial of degree one here, then we can just get this exact 0 values or this polynomial just providing us also a polynomial of degree one which is exact or error term is zero for this polynomial of degree one here.

(Refer Slide Time: 21:44)

For $f(x) = 1$, $\int_a^b f(x) dx - \frac{b-a}{2} [f(a) + f(b)] = R_n(f)$.

$$R(f, x) = \int_a^b 1 dx - \frac{b-a}{2} [1 + 1]$$

$$= b - a - \frac{b-a}{2} \times 2 = 0.$$

$f(x) = x$, $\int_a^b x dx - \frac{b-a}{2} [a + b] = R(f, x)$

$$\Rightarrow \frac{x^2}{2} \Big|_a^b - \frac{b-a}{2} (a+b) = R(f, x)$$

$$\Rightarrow 0 = R(f, x).$$

For $f(x) = x^2$, $C = \int_a^b x^2 dx - \frac{b-a}{2} [a^2 + b^2]$.

So that is why immediate to the next if you just consider this polynomial that is in the form of x equals to x square here or f of x equals to x square here then we can just get this error term here. If you just put f of x equals to x square here, C can be written as integration a to b , so

first function that is $x^2 dx$ minus summation or you can just use this formula for this trapezoidal rule here that can be written also as, $\frac{b-a}{2}$ and f of x is x^2 here, so we can just write a^3 plus b^3 here.

(Refer Slide Time: 22:25)

Numerical Integration

Error Estimate in Trapezoidal Rule:

It can be verified that the trapezium rule gives the exact value of the integration for polynomials of degree ≤ 1 . i.e. $R(f, x) = 0$ for $f(x) = 1, x$

For $f(x) = 1$: $R(f, x) = \int_a^b 1 dx - \frac{(b-a)}{2} 2 = (b-a) - (b-a) = 0$

For $f(x) = x$: $R(f, x) = \int_a^b x dx - \frac{(b-a)}{2} (b+a) = \frac{1}{2} (b^2 - a^2) - \frac{1}{2} (b^2 - a^2) = 0$

For $f(x) = x^2$: $C = \int_a^b x^2 dx - \frac{(b-a)}{2} (b^2 + a^2) = \frac{1}{3} (b^3 - a^3) - \frac{1}{2} (b^3 + a^2b - ab^2 - a^3)$

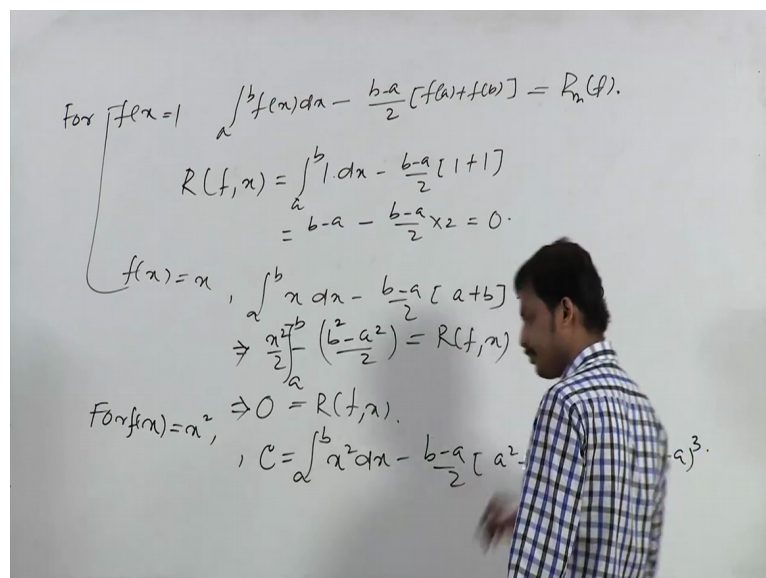

$$= \frac{1}{6} (a^3 - 3a^2b + 3ab^2 - b^3) = -\frac{1}{6} (b-a)^3$$

* The order of trapezoidal rule is 1(one).

NPTEL ONLINE
CERTIFICATION COURSE

11

If you will just solve this equations here that is x^3 by 3 it will just come, so you can just write b^3 by 3 minus a^3 by 3, first one or if you will put this values all of this values here that is in the form of like x to the power 3 by 3 here, then put all of this ranges here then you can just obtain the C value as minus of 1 by 6, b minus a whole cube here.

(Refer Slide Time: 23:06)

Numerical Integration

Using the definition of error the error is given by

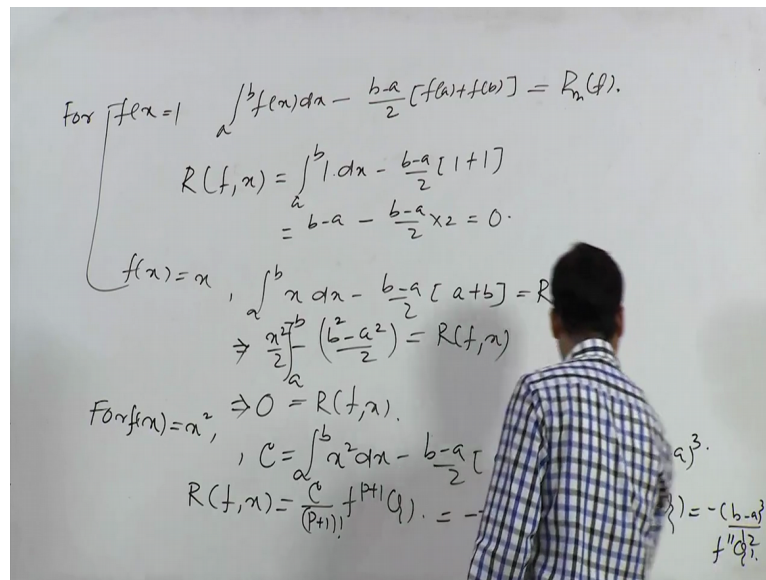

$$R(f, x) = \frac{C}{2!} f''(\xi) = -\frac{(b-a)^3}{12} f''(\xi) \quad ; a \leq \xi \leq b$$

The bound of the error is given by

$$|R(f, x)| \leq \frac{(b-a)^3}{12} \max_{a \leq x \leq b} |f''(x)| \quad \dots(1.10)$$

□ If the length of the interval $[a, b]$ is large, then $(b-a)$ is also large and so the error term in expression (1.10) will be large. Thus the method becomes meaningless.

12

And if you will just put this C value in the error term here, so usually this are R of f of x for this one it can be written as, C by p plus 1 factorial, f to the power p plus 1 zeta. So p is especially 1 here, so that is why we can just write that one as, minus 1 by 6, b minus a whole cube, 1 by 2 here, f to the power double dash of zeta. Which can just give you here minus of if you will just see here minus of b minus a whole cube by 12, f double dash of zeta, where zeta should be lies between a and b.

Numerical Integration

Using the definition of error the error is given by

$$R(f, x) = \frac{c}{2!} f''(\xi) = -\frac{(b-a)^3}{12} f''(\xi) \quad ; a \leq \xi \leq b$$

The bound of the error is given by

$$|R(f, x)| \leq \frac{(b-a)^3}{12} \max_{a \leq x \leq b} |f''(x)| \quad \dots(1.10)$$

□ If the length of the interval $[a, b]$ is large, then $(b-a)$ is also large and so the error term in expression (1.10) will be large. Thus the method becomes meaningless.

12

And if you will just go for this maximum bound of this error this can be written as R of f of x in magnitude form this will be less or equal to b minus a whole cube by 12, maximum of f double dash of x . And from this formula we can just visualize that if the length is larger suppose then we can just obtain this b minus a difference is also large and in that case this method becomes meaningless, if the like the section is very small then we will have good result.

Numerical Integration

Example on Trapezoidal Rule

Calculate the value of $\int_0^1 \frac{x}{1+x} dx$ taking $h=1$ using Trapezoidal rule. Also find the exact value of the integral and the error.

Solution: Here $a=0$, $b=1$, $f(x)=x/(1+x)$,
Therefore, $f(0)=0$ and $f(1)=1/2$. Thus

$$I = \frac{(b-a)}{2} [f(a) + f(b)] = \frac{(1-0)}{2} \left[0 + \frac{1}{2} \right] = \frac{1}{2} \times \frac{1}{2} = \frac{1}{4} = 0.25$$

Exact solution is

$$\int_0^1 \frac{x}{1+x} dx = \int_0^1 \left(1 - \frac{1}{1+x} \right) dx = [x - \log(1+x)]_0^1 = 1 - \log 2 = 1 - 0.3010 = 0.6990$$

Hence the error is $(0.6990 - 0.25) = 0.4490$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

13

So then if you will go for example of trapezoidal rule here, so if the question is asked suppose find the value of integration 0 to 1, x by 1 plus x dx . We have just consider a simple example

here taking h equals to 1 using trapezoidal rule than how we can just implement this formula that I will just discuss, also we can just find this exact value of integrals since it is a simple function I have just consider we can easily get this exact value and then we can just obtain the error by taking this approximated value calculated by using trapezoidal rule and exact value calculating in numerical form or analytical form.

(Refer Slide Time: 25:19)

$$\int_0^1 \frac{x}{1+x} dx, \quad h=1.$$

$$a=0, \quad b=1 \quad f(x) = \frac{x}{1+x}, \quad h=1. \quad h = \frac{b-a}{n}$$

$$1 = \frac{1-0}{n}$$

$$n=1.$$

$$\int_0^1 \frac{x}{1+x} dx = \frac{1-0}{2} \left[0 + \frac{1}{2} \right]$$

$$= \frac{1}{2} \times \frac{1}{2} = \frac{1}{4} = 0.25$$

Suppose this integration is asked 0 to 1, x by 1 plus x dx here and this space size that is given as I think one here. So using trapezoidal rule solve this integral equation here if you just see here, so a equals to 0 here, b equals to 1, f of x equals to x by 1 plus x and space size h equals to 1 means n equals to 1 here. Usually we are just defining h equals to b minus a by n here, so that is h is given as 1, so 1 minus 0 by h here, so that is why we can just consider sorry n , so n equals to 1 here.

So we can just use trapezoidal rule by considering all this values whatever it has just given to us. So if you just use them we can just write integration 0 to 1, x by 1 plus x into dx , using trapezoidal rule this can be b minus a by 2, 1 minus 0 by 2, f of a , that is if you if I will just put here 0 that will especially give you 0 value here plus 1 by 2 here. And this can be written as 1 by 2 into 1 by 2 that is 1 by 4 here or especially we can just write this one as 0.25.

(Refer Slide Time: 27:05)

$$\int_0^1 \frac{x}{1+x} dx, \quad h=1.$$

$$a=0, b=1, f(x) = \frac{x}{1+x}, \quad h=1, \quad h = \frac{b-a}{n}.$$

$$\int_0^1 \frac{x}{1+x} dx = \frac{1-0}{2} \left[0 + \frac{1}{2} \right] \quad L = \frac{1-0}{n} = \frac{1}{n}, \quad n=1.$$

$$= \frac{1}{2} \times \frac{1}{2} = \frac{1}{4} = 0.25$$

$$\int_0^1 \left(1 - \frac{1}{1+x} \right) dx = \left[x - \ln(1+x) \right]_0^1 = 1 - \ln 2 = 0.6990.$$

Numerical Integration

Example on Trapezoidal Rule

Calculate the value of $\int_0^1 \frac{x}{1+x} dx$ taking $h=1$ using Trapezoidal rule. Also find the exact value of the integral and the error.

Solution: Here $a=0$, $b=1$, $f(x)=x/(1+x)$,
 Therefore, $f(0)=0$ and $f(1)=1/2$. Thus

$$I = \frac{(b-a)}{2} [f(a) + f(b)] = \frac{(1-0)}{2} \left[0 + \frac{1}{2} \right] = \frac{1}{2} \times \frac{1}{2} = \frac{1}{4} = 0.25$$

Exact solution is

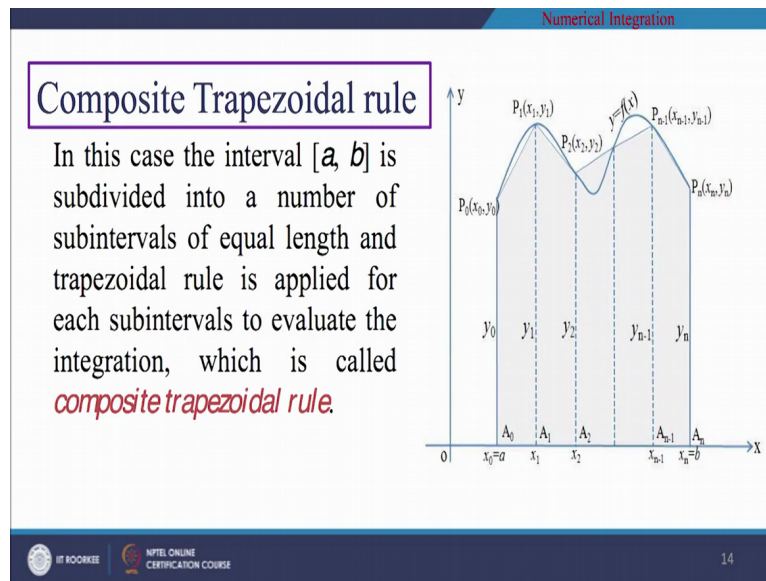

$$\int_0^1 \frac{x}{1+x} dx = \int_0^1 \left(1 - \frac{1}{1+x} \right) dx = \left[x - \log(1+x) \right]_0^1 = 1 - \log 2 = 1 - 0.3010 = 0.6990$$

Hence the error is $(0.6990 - 0.25) = 0.4490$

13

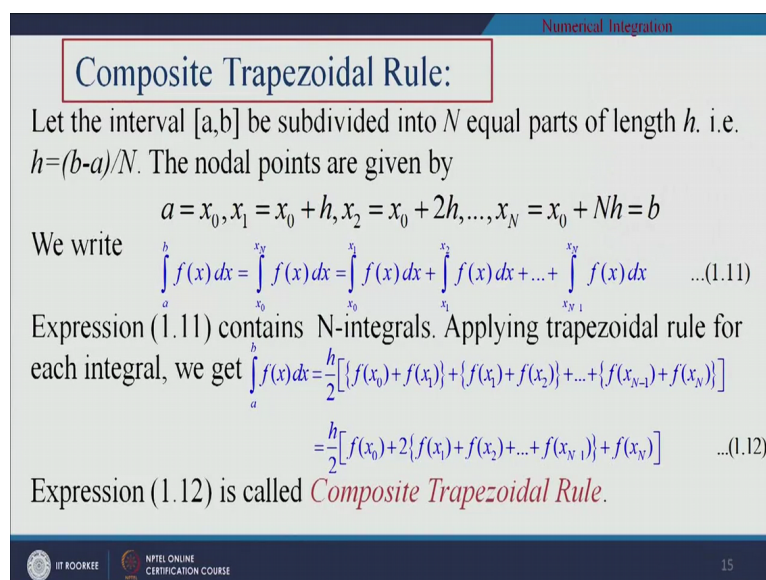

And if you will just go for this analytical solution here I can just write this one as 0 to 1, 1 minus I think 1 by 1 plus x here into dx and this can be written as like x minus ln of 1 plus x, 0 to 1 range here. So it can be written as like 1 minus (ln 2) (27:24) or L n 2, I can just say and this value is just giving you like 0.6990 here. And if you will just this difference then we can just find this error that is 0.6990 minus 0.25 the error is coming as 0.4490 here, since we are just taking h sizes is larger here that is why this error is very high.

(Refer Slide Time: 27:53)

So then we will just go for composite trapezoidal rule, so in each of this interval we can just form a trapezoid it and then we can just approximate this integration in each of this ranges there that is basically called the composite trapezoidal rule here. So graphically you can just say that in each of this section a trapezium is formed there and area this trapezium is approximated in each of this intervals and then we can just combine each of this intervals and then in a composite form we can just obtain a composite formula.

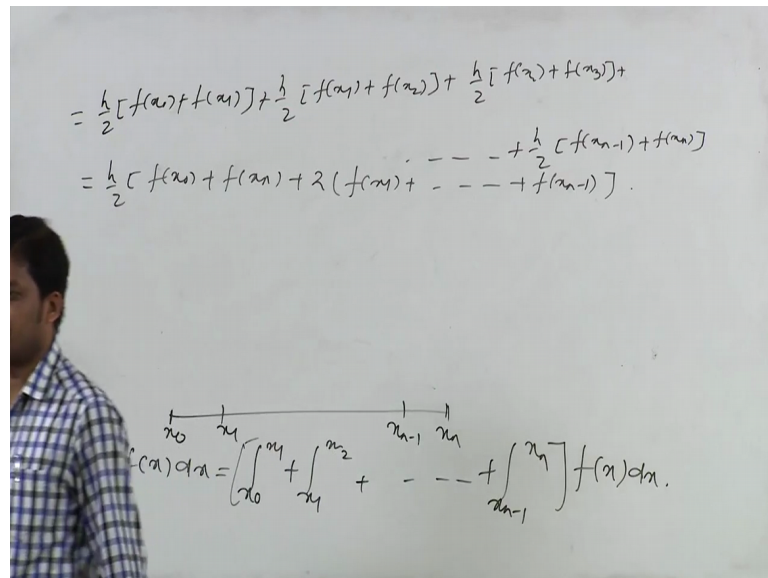

(Refer Slide Time: 28:28)

So if you will just consider this space sizes are all are equal here this means that if you will just starts from x_0 , x_1 , to x_n here, so if you will just use this one this formula like a to b , f

of $x \, dx$ here, then we can just write this one as x_0 to x_1 , x_1 to x_2 upto x_{n-1} to x_n , f of $x \, dx$ here.

(Refer Slide Time: 29:09)

$$= \frac{h}{2} [f(x_0) + f(x_1)] + \frac{h}{2} [f(x_1) + f(x_2)] + \frac{h}{2} [f(x_2) + f(x_3)] + \dots + \frac{h}{2} [f(x_{n-1}) + f(x_n)]$$

$$= \frac{h}{2} [f(x_0) + f(x_n) + 2(f(x_1) + f(x_2) + \dots + f(x_{n-1}))]$$

$$\int_{x_0}^{x_n} f(x) \, dx = \int_{x_0}^{x_1} f(x) \, dx + \int_{x_1}^{x_2} f(x) \, dx + \dots + \int_{x_{n-1}}^{x_n} f(x) \, dx$$

And each of intervals if you just write this formula here then we can just rewrite this formulation as, so 1st interval we can just write h by 2, f of x_0 plus f of x_1 here, 2nd interval we can just write h by 2, f of x_1 plus f of x_2 , 3rd interval we can just write h by 2, f of x_2 plus f of x_3 plus the last interval if you will just write here f of x_{n-1} plus f of x_n here.

So if you will just add up all this terms here we can just write this one as h by 2, f of x_0 plus f of x_n plus 2 into f of x_1 to f of x_{n-1} , this is basically called composite trapezoidal formula here. So with this I am just completing this lecture next lecture I will just go for this error computation of trapezoidal rule, thank you for the listening the lecture.
