Solution of Non-Homogeneous Linear System with Constant Coefficients

Hello friends welcome to the lecture on solution of non-homogeneous linear system with constant coefficients.

(Refer Slide Time: 00:31)

Fundamental matrix solution: if $x^1(t), \dots, x^n(t)$ are n linearly independent solutions of the differential equation

$$\dot{x} = Ax. \tag{1}$$

Then every solution $x(t)$ can be written in the form

$$x(t) = c_1 x^1(t) + \dots + c_n x^n(t). \tag{2}$$

Let $X(t)$ be a matrix whose columns are $x^1(t), \dots, x^n(t)$. Then (2) can be written in a concise form $x(t) = X(t)c$, where $c = [c_1, c_2, \dots, c_n]^T$.

Definition: A matrix $X(t)$ is called a fundamental matrix solution of (1) if its columns form a set of n linearly independent solutions of (1).

$X(t)c = \begin{bmatrix} x^1(t) & x^2(t) & \dots & x^n(t) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ \vdots \\ c_n \end{bmatrix} = c_1 x^1(t) + c_2 x^2(t) + \dots + c_n x^n(t)$

2

Suppose $x_1(t)$, $x_2(t)$, and so on $x_n(t)$ are n linearly independent solutions of the vector differential equation $\dot{x} = Ax$. Now we have already discussed how to find n linearly independent solutions of this homogeneous vector differential equation so suppose $x_1(t)$, $x_2(t)$ and so on $x_n(t)$ are n linearly independent solutions of the vector differential equation.

$\dot{X} = AX$ then every solution $x(t)$ of the vector differential equation $\dot{x} = Ax$ can be written in the form $x(t) = c_1 * x_1(t) + c_2 * x_2(t)$ and so on $c_n * x_n(t)$ where c_1, c_2, c_n are constants. Let $X(t)$ be a matrix whose columns are these n independent solutions $x_1(t), x_2(t)$ and so on $x_n(t)$. Then (2) can be written in the concise form $x(t) = X(t) * c$, you can write it like this, see $X(t) = x_1(t), x_2(t)$ and so on $x_n(t)$, okay.

Now when you find out $x(t) * c$ what do we get $x(t) * c = x_1(t) x_2(t) x_n(t)$ multiplied by the column vector c_1, c_2, c_n , okay. Now these $x_1(t), x_2(t), x_n(t)$ are themselves column vectors okay, so when you multiply c_1, c_2, c_n and this is $n * n$ matrix. $X(t)$ is $n * n$ matrix whose first

column is $x_1(t)$, second column is $x_2(t)$ and the last column is $x_n(t)$, okay, so when you multiply this $n \times n$ matrix by c_1, c_2, c_n what you get is $x(t) = X(t)c$, okay.

So this is $x(t) = X(t)c$ is a column vector okay and it is equal to $n \times n$ matrix your $X(t)$ and multiplied by c vector, okay, so this is nothing but this is $= c_1$ times $x_1(t) + c_2$ times $x_2(t)$ and so on c_n times $x_n(t)$. So it is the general solution of the vector differential equation $\dot{x} = Ax$. Now a matrix $X(t)$ is called a fundamental matrix solution of the vector differential equation $\dot{x} = Ax$ if it is columns form a set of n linearly independent solutions of 1.

So $X(t)$ here which comprises of these n linearly independent solutions $x_1(t), x_2(t), x_n(t)$ is the fundamental matrix solution of equation 1. Now you can write these n vectors in any order so there is not a unique fundamental matrix, any matrix okay where the n columns are n linearly independent solutions of the vector differential equation $\dot{x} = Ax$ will always be called as a fundamental matrix solution of the vector differential equation.

So $X(t)$ here is the fundamental matrix. Now let us consider a vector differential equation $\dot{x} = Ax$ okay.

(Refer Slide Time: 04:20)

Example: Let $\dot{x} = \begin{bmatrix} 1 & -1 & 4 \\ 3 & 2 & -1 \\ 2 & 1 & -1 \end{bmatrix} x$

Then $x^1(t) = e^t \begin{bmatrix} -1 \\ 4 \\ 1 \end{bmatrix}$, $x^2(t) = e^{3t} \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$ and $x^3(t) = e^{-2t} \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$

are three linearly independent solutions of the given vector differential equation.

Handwritten notes:
 $A = \begin{bmatrix} 1 & -1 & 4 \\ 3 & 2 & -1 \\ 2 & 1 & -1 \end{bmatrix}$
 $|A - \lambda I| = 0 \Rightarrow \lambda = 1, 3, -2$
 Eigen vector for $\lambda = 1$ is $\begin{bmatrix} 1 \\ 4 \\ 1 \end{bmatrix}^T$
 Eigen vector for $\lambda = 3$ is $\begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}^T$
 Eigen vector for $\lambda = -2$ is $\begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}^T$
 $x^1(t) = e^t \begin{bmatrix} -1 \\ 4 \\ 1 \end{bmatrix}$
 $x^2(t) = e^{3t} \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$
 $x^3(t) = e^{-2t} \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$
 $X(t) = \begin{bmatrix} x^1(t) & x^2(t) & x^3(t) \\ -e^t & e^{3t} & -e^{-2t} \\ 4e^t & 2e^{3t} & e^{-2t} \\ e^t & e^{3t} & e^{-2t} \end{bmatrix}$
 $x^1(0) = \begin{bmatrix} -1 \\ 4 \\ 1 \end{bmatrix}^T$, $x^2(0) = \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}^T$
 $x^3(0) = \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}^T$

IF ROOKIE | NPTEL ONLINE CERTIFICATION COURSE | 3

So A is this 3×3 matrix $\begin{bmatrix} 1 & -1 & 4 \\ 3 & 2 & -1 \\ 2 & 1 & -1 \end{bmatrix}$. In order to find a fundamental matrix of this vector differential equation what we do is, we first find 3 linearly independent solutions of this vector differential equations, so for this we first write the characteristic equation of the matrix A , determinant $A - \lambda I = 0$, it will give you a cubic equation in λ so when you solve that cubic equation in λ you will get the values of λ as 1, 3 and -2.

You can see the 3 values of λ are real and distinct and therefore the corresponding eigen vectors will be linearly independent. For $\lambda = 1$ you can check that for $\lambda = 1$ eigen vector for $\lambda = 1$ is $[-1, 4, 1]^T$ okay, and similarly eigen vector for $\lambda = 3$ will come out to be $[1, 2, 1]^T$ and eigen vector for $\lambda = -2$ is $[-1, 1, 1]^T$ okay.

Now we know that if λ is an eigen value of the matrix A and v is the corresponding eigen vector then $e^{\lambda t} v$ is the solution of the homogeneous vector differential equation $\dot{x} = Ax$, so here $x_1(t) = e^t [-1, 4, 1]^T$ that is e^t to the power t * $[-1, 4, 1]^T$ which is an eigen vector corresponding to $\lambda = 1$, this is one solution of the vector differential equation other solution corresponds to the other eigen value.

And the corresponding eigen vector $\lambda = 3$ so e^{3t} and then you have $[1, 2, 1]^T$ and $x_3(t) = e^{-2t} [-1, 1, 1]^T$, okay, these 3 eigen vectors, these 3 solutions $x_1(t), x_2(t), x_3(t)$ of the vector differential equations are linearly independent because their values at $t = 0$, $x_1(0)$ is $[-1, 4, 1]^T$, $x_2(0)$ is $[1, 2, 1]^T$, $x_3(0)$ is $[-1, 1, 1]^T$, okay, the 3 vectors $x_1(0), x_2(0), x_3(0)$ are linearly independent because they are eigen vectors corresponding to the distinct eigen values 1, 3, -2.

So these 3 vectors are linearly independent and therefore $x_1(t), x_2(t), x_3(t)$ are linearly independent solutions of the given vector differential equation okay. Now we can write a fundamental matrix. Fundamental matrix $X(t)$ will be $[x_1(t), x_2(t), x_3(t)]$, let us take first column $x_1(t), x_2(t), x_3(t)$, okay, then $x_1(t)$, you multiple e^t to the power t inside so $-e^t$ to the power t , $4e^t$ to the power t and e^t to the power t .

So you get $-e^t$ to the power t , $4e^t$ to the power t , and e^t to the power t , this is first column. Second column similarly e^{3t} , $2e^{3t}$, and then e^{3t} , this is second column and third column will be here $-e^{-2t}$, e^{-2t} and e^{-2t} . So this is how we form a fundamental matrix of solution of $\dot{x} = Ax$, so $X(t)$ is this matrix.

(Refer Slide Time: 08:45)

Hence

$$X(t) = \begin{bmatrix} -e^t & e^{3t} & -e^{-2t} \\ 4e^t & 2e^{3t} & e^{-2t} \\ e^t & e^{3t} & e^{-2t} \end{bmatrix}$$

is a fundamental matrix solution of the given system.

It is a fundamental matrix solution of the given system.

(Refer Slide Time: 08:50)

Now in our next result, we shall see that the matrix

$$e^{At} = I + At + \frac{A^2 t^2}{2!} + \dots + \frac{A^n t^n}{n!} + \dots$$

can be computed directly from any fundamental matrix solution of (1).

Theorem: Let $X(t)$ be a fundamental matrix of solution of the differential equation (1). Then,

$$e^{At} = X(t)X^{-1}(0), \quad (3)$$

i.e. the product of any fundamental matrix of solution of (1) with its inverse at $t=0$ yields e^{At} .

$$X(t) = [x^1(t) \ x^2(t) \ \dots \ x^n(t)] \quad X^{-1}(0) = [X(0)]^{-1}$$

Now we have seen that e to the power At where A is $n \times n$ matrix is given by this series $I + At + \frac{A^2 t^2}{2!} + \dots$ and so on. e to the power At is not easy to compute from this expansion, $I + At + \frac{A^2 t^2}{2!} + \dots$ and so on, but we will see in the theorem which we are going to now state that it can be computed directly from any fundamental matrix solution of the vector differential equation $\dot{x} = Ax$.

The theorem is like this, let $X(t)$ be a fundamental matrix solution of differential equation 1 then e to the power At is $X(t) \cdot X(0)^{-1}$. $X(0)^{-1}$ is, I mean to say the matrix $X(0)$ inverse okay, so $X(0)^{-1}$ is the inverse of the matrix $X(0)$ that is when you know the matrix

$X(t)$ just put $t = 0$ there so then $X(0)$ will be $= x_1(0) \ x_2(0)$ and so on $x_n(0)$. So this matrix n/n matrix you will get, you find the inverse of this $X(0)$ to get this $X^{-1}(0)$, $(())$ $(10:22)$ 0 inverse.

So in order to determine the matrix e to the power At we need to know a fundamental matrix of the vector differential equation and then the inverse of the matrix $X(0)$ okay, so the product of the 2 will then give e to the power At .

(Refer Slide Time: 10:42)

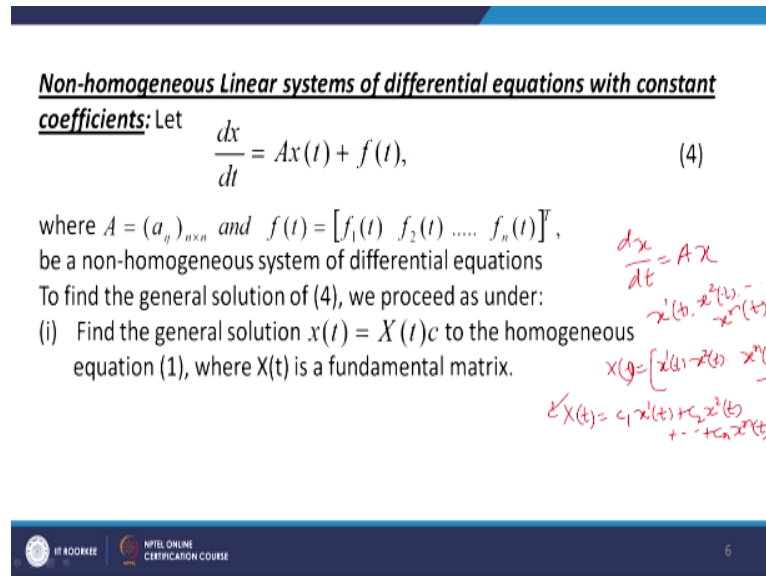

Non-homogeneous Linear systems of differential equations with constant coefficients: Let

$$\frac{dx}{dt} = Ax(t) + f(t), \quad (4)$$

where $A = (a_{ij})_{n \times n}$ and $f(t) = [f_1(t) \ f_2(t) \ \dots \ f_n(t)]^T$,
 be a non-homogeneous system of differential equations
 To find the general solution of (4), we proceed as under:

(i) Find the general solution $x(t) = X(t)c$ to the homogeneous equation (1), where $X(t)$ is a fundamental matrix.

Handwritten notes:
 $\frac{dx}{dt} = AX$
 $x(t) = x_1^{(1)}(t) \dots x_n^{(1)}(t)$
 $X(t) = [x_1^{(1)}(t) \ x_2^{(1)}(t) \ \dots \ x_n^{(1)}(t)]$
 $X(t) = c_1 x_1^{(1)}(t) + c_2 x_2^{(1)}(t) + \dots + c_n x_n^{(1)}(t)$

Now let us consider a non-homogenous linear system of differential equation with constant coefficients. So let us say we consider $dx/dt = Axt + ft$ where A is n/n matrix A_{ij} and cross n and ft is a column vector with components x_1, f_1t, f_2t and so on f_1t . Earlier we considered only homogenous equations where we took this ft as a 0 vector. Now after that we have tackled the homogenous linear systems of differential equations with constant coefficients.

Now let us consider the case of an non-homogenous linear system of differential equation with constant coefficients. Now so in order to find the general solution of this equation 4 what we do is we proceed in the following manner. First we find the general solution which we write as $Xt = Xt * c$ to the homogeneous equation 1 okay, so homogeneous equation 1 is what $dx/dt = Ax$ okay.

The homogeneous equation corresponding to the nonhomogeneous linear system 4 is $dx/dt = Ax$ so we find general solution of this that means we find n linearly independent solutions x_1t, x_2t and so on, xnt of this homogeneous linear system and then form the fundamental

matrix we have discussed just now fundamental matrix $x(t) = x_1(t), x_2(t)$ and so on $x_n(t)$ whose n columns are these n linearly independent solutions of $dx/dt = Ax$.

So this is fundamental matrix and we then multiply this $x(t)/c$ okay to get the general solution. So $c * x(t)$ as we have seen earlier there is nothing but $c_1 x_1(t) + c_2 x_2(t)$ and so on $c_n x_n(t)$. So first we find the n linearly independent solutions of the vector differential equation $dx/dt = Ax$ and then write the general solution okay, $c_1 x_1(t) + c_2 x_2(t)$ and so on $c_n x_n(t)$ which in a concise form can be written as $c * X(t)$.

So we find this general solution of the homogeneous equation $X \dot{=} Ax$ and then we find particular solution $X_p(t)$ we write it as $X_p(t)$ to this nonhomogeneous system okay.

(Refer Slide Time: 13:30)

(ii) Find a particular solution $x_p(t)$ to (4). The general solution to the non-homogeneous equation (4) is then given by

$$x(t) = x_c(t) + x_p(t).$$

The solution of the IVP

$$\dot{x} = Ax(t) + f(t), x(t_0) = x_0 \tag{5}$$

is obtained from the general solution by determining the constant vector c with the help of $x(t_0) = x_0$.

The following theorem gives one way to find a particular solution based on a fundamental matrix.

Handwritten notes:
 $\frac{d}{dt} x(t) = Ax(t) + f(t)$
 $\frac{d}{dt} \{c_1 x_1(t) + c_2 x_2(t)\} = \frac{d}{dt} c_1 x_1(t) + \frac{d}{dt} c_2 x_2(t) = A x_1(t) + A x_2(t) + f(t) = A(x_1(t) + x_2(t)) + f(t) = A x_c(t) + f(t)$
 $x(t)$ is a solution of (4)
 $x(t) = X(t)c + x_p(t)$
 $c = [c_1, c_2, \dots, c_n]^T$

Equation for initial condition:
 $x_0 = X(t_0)c + x_p(t_0)$

So then the combination of the 2 $x_c(t)$ and $x_p(t)$ okay, will give us the general solution of the nonhomogeneous system 4 okay, nonhomogeneous system 4 will have the general solution given by $x(t) = x_c(t) + x_p(t)$. Now let us see how, first we see that it is a solution of the system 4 and then we see that it is a general solution. So let us first show how it is a solution of 4 okay. So let us in the system 4, let us put $x(t) = Ax c(t) + x_p(t)$.

So this is your $dx/dt = Ax + f(t)$ let us put in that so we have d/dt this is our system so first we show that $x(t) = Ax c(t) + x_p(t)$ is the solution of this so d/dt let us take the lefthand side, let us put for $x(t)$, $x_c(t) + x_p(t)$. Then d/dt of $x_c(t) + x_p(t)$ we know if this is d/dt of $x_c(t) + d/dt$ of $x_p(t)$, now $x_c(t)$ is the general solution of the homogenous system $dx/dt = Ax$ so we get here d/dt of $x_c(t) = Ax c(t) + x_p(t)$ is a particular solution of this system 4.

So $\frac{d}{dt}$ of $x_p(t)$ will be equal to $Ax_p(t) + f(t)$. Now let us combine this can be written as $Ax_c(t) + x_p(t) + f(t)$ and this will be $= x_c(t) + x_p(t) = x(t)$ so we have $Ax(t) + f(t)$. So $x(t) = x_c(t) + x_p(t)$ satisfies the system (4) and therefore $x(t)$ is the solution of (4). Now we see that we know that $x_c(t) = x_c(t) + x_p(t)$ contains n constants in the solution $x_c(t)$ of the homogenous system so this solution $x(t) = x_c(t) + x_p(t)$ contains an arbitrary constants c_1, c_2, \dots, c_n .

And therefore $x(t)$ is the general solution of this nonhomogeneous system $\frac{dx}{dt} = Ax(t) + f(t)$. Now when we want to find the particular solution of the initial value problem. So let us consider $\dot{x} = Ax(t) + f(t)$ where at t_0 we assume that $x(t)$ has the value $x(t_0)$ not then the solution for this initial value problem is obtained by calculating the constant vector c that occurs in $x_c(t)$ okay. We have $x(t) = x_c(t) + x_p(t)$ that means $x(t) = X(t) \cdot c + x_p(t)$, this constant vector c which we have taken as c_1, c_2, \dots, c_n .

So this constant vector c is calculated by using the value of $x(t)$ at $t = t_0$. When you put $t = t_0$ here we get $x(t_0) = X(t_0) \cdot c + x_p(t_0)$, okay, so this c is calculated from here and then we put the value of c in this solution $x(t) = X(t) \cdot c + x_p(t)$ to arrive at a particular solution of the initial value problem. Now the question arises how we find particular solution of the system (4) okay.

(Refer Slide Time: 17:54)

Theorem: Let $X(t)$ be a fundamental matrix of (1), a particular solution to (4) is given by

$$x_p(t) = \int X(t) \{X(s)\}^{-1} f(s) ds.$$

$$\begin{aligned} \frac{dx}{dt} &= Ax(t) + f(t) \\ \frac{dx}{dt} &= AX \\ X(t) &= [x^1(t) \quad x^2(t) \quad \dots \quad x^n(t)] \end{aligned}$$

So we state a formula for this particular solution of system (4), let $X(t)$ be a fundamental matrix, so in order to find particular solution to the system (4) we need to know the fundamental matrix of (4) that is let us recall we have the system $\frac{dx}{dt} = Ax(t) + f(t)$. So this theorem tells us a

particular solution x_{pt} can be found once you know a fundamental matrix of the homogenous system $dx/dt = Ax$.

That is $Xt = x_{1t} x_{2t}$ and so on x_{nt} so if you have a fundamental matrix for the system $dx/dt = Ax$ then that fundamental matrix you put here inside the integral so you have Xt then you find the inverse the matrix x_t so that is Xs is the variable of integration here so inverse of the matrix x_t you need to find. Now remember x_{1t} , x_{2t} or x_{nt} are n linearly independent solutions of $dx/dt = Ax$, so x_t is a non-singular matrix and therefore we can find its inverse.

So we find inverse of this matrix x_t and put here the value of Xs inverse and then multiply by f this vector f is known to us and then integrate with respect to s . So we shall get the matrix, we will get the particular solution of equation 4, okay, so we know x_{pt} and then we add x_{ct} the general solution of $dx/dt = Ax$ to that and have the general solution $Ax_t = x_{ct} + x_{pt}$ of the system 4. So let us see how we go about it.

(Refer Slide Time: 20:00)

Example 1: Let $\dot{x} = \begin{bmatrix} \frac{6}{7} & -\frac{15}{14} \\ -\frac{5}{7} & \frac{37}{14} \end{bmatrix} x + \begin{bmatrix} e^{2t} \\ e^{-t} \end{bmatrix}$, $x(0) = [4 \ -1]^T$

The eigen values of A are $\frac{1}{2}, 3$.
 Eigen vector for $\lambda_1 = \frac{1}{2}$: $v_1 = [3 \ 1]^T$ ✓

Eigen vector for $\lambda_2 = 3$: $v_2 = [-1 \ 2]^T$ ✓

Thus,

$$X(t) = \begin{bmatrix} 3e^{t/2} & -e^{3t} \\ e^{t/2} & 2e^{3t} \end{bmatrix}$$
 ✓

$A = \begin{bmatrix} \frac{6}{7} & -\frac{15}{14} \\ -\frac{5}{7} & \frac{37}{14} \end{bmatrix}$ $f(t) = \begin{bmatrix} e^{2t} \\ e^{-t} \end{bmatrix}$
 $x(0) = \begin{bmatrix} 4 \\ -1 \end{bmatrix}$
 $|A - \lambda I| = 0 \Rightarrow \lambda_1 = \frac{1}{2}, \lambda_2 = 3$
 $X(t) = \begin{bmatrix} x^1(t) & x^2(t) \end{bmatrix}$
 $= \begin{bmatrix} e^{\frac{1}{2}t} \begin{bmatrix} 3 \\ 1 \end{bmatrix} & e^{3t} \begin{bmatrix} -1 \\ 2 \end{bmatrix} \end{bmatrix}$
 $= \begin{bmatrix} 3e^{\frac{1}{2}t} & -e^{3t} \\ e^{\frac{1}{2}t} & 2e^{3t} \end{bmatrix}$

9

Let us take an example $\dot{x} = Ax + ft$ so A here is this matrix $6/7-15/14$ and then $-5/7$ and we have $37/14$ this is matrix A and f is = the vector e to the power $2t$, e to the power $-t$. Now we have initial value problem so we are given that when $t \neq 0$ $x(t_0)$ is x not that is the vector $4-1$ so we have $x_0 = 4-1$. So first we will find the general solution of the nonhomogeneous system $\dot{x} = Ax + ft$ and then use the initial condition $x_0 = 4-1$ to arrive at the solution of this initial value problem.

Now it is easy to see that determinant of $A - \lambda I = 0$ gives us $\lambda = 1/2$ and $\lambda = 3$. So $\lambda_1 = 1/2$ $\lambda_2 = 3$. So we get the 2 eigen values which are real and distinct, okay, so the eigen values are real and distinct. We can find eigen vectors corresponding to $\lambda_1 = 1/2$ and $\lambda_2 = 3$ since the eigen values are real and distinct the corresponding eigen vectors are orthogonal.

So v_1 and v_2 we can find they are orthogonal, they are linearly independent okay. Now what we have $X(t)$, $X(t)$ is the fundamental matrix, so $X(t) = x_1(t) x_2(t)$. So these eigen values are real and distinct, so $x_1(t)$ will be e to the power $\lambda_1 t$ that is e to the power $1/2 t$, this is $x_1(t)$ and $x_2(t)$ will be e to the power $3t$, e to the power $\lambda_2 t$, so -12 and you can see this will be equal to $3 e$ to the power $1/2 t$, e to the power $1/2 t$, $-e$ to the power $3t$ and $2 e$ to the power $3t$.

So we get this fundamental matrix, okay now what we do.

(Refer Slide Time: 22:29)

Hence,

$$x_c(t) = \begin{bmatrix} 3c_1 e^{t/2} - c_2 e^{3t} \\ c_1 e^{t/2} + 2c_2 e^{3t} \end{bmatrix}$$

Now,

$$x_p(t) = \int X(t) \{X(s)\}^{-1} f(s) ds,$$

and

$$\{X(t)\}^{-1} = \begin{bmatrix} \frac{2}{7} e^{-t/2} & \frac{1}{7} e^{-t/2} \\ -\frac{1}{7} e^{3t} & \frac{3}{7} e^{3t} \end{bmatrix}$$

Hence

$$x_p(t) = \frac{1}{7} \begin{bmatrix} 3e^{2t} - \frac{5}{4} e^{-t} \\ \frac{10}{3} e^{2t} - \frac{13}{6} e^{-t} \end{bmatrix}$$

$x_c(t) = X(t)c = \begin{bmatrix} 3e^{t/2} & -e^{3t} \\ e^{t/2} & 2e^{3t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix}$

$\dot{x} = Ax + f(t)$

$|X(t)|$

$\{X(t)\}^{-1} = \frac{\text{adj } X(t)}{|X(t)|}$

$f(t) = \begin{bmatrix} e^{2t} \\ e^{-t} \end{bmatrix}$

IIT ROORKEE

NTEL ONLINE CERTIFICATION COURSE

10

Once we have $X(t)$ with us, fundamental matrix with us we can write $x(t)$. So $x(t) = X(t)c$ where $X(t)$ is $3 e$ to the power $t/2$ and second column is this one what is that $-e$ to the power $3t$, $2 e$ to the power $3t$ multiplied by the vector $c_1 c_2$ okay, so when you multiply this column vector to this $2/2$ matrix you get $3 c_1 e$ to the power $t/2 - c_2 e$ to the power $3t$, this one first element and second element is $c_1 e$ to the power $t/2$ and then $2c_2 e$ to the power $3t$.

So we get this general solution of the vector equation $\dot{x} = Ax$. Now let us find a particular solution of $\dot{x} = Ax + f(t)$ so particular solution by our theorem is given by $X(t) * X(s)^{-1} * \int X(s) f(s) ds$.

fs. Now X_t , X_t we know this is our X_t , this is our X_t , we can find it is determinant since the vectors x_{1t} and x_{2t} are linearly independent this matrix is determinant is nonzero okay, so we can find determinant of this matrix x_t .

We can find adjoint of the matrix x_t and then find x_t inverse. So x_t inverse is adjoint of the matrix x_t /determinant of x_t . Now when you do this you will get this matrix. X_t inverse = $2/7 e$ to the power $-t/2$ $1/7 e$ to the power $-t/2$ $-1/7 e$ to the power $3t$ $3/7 e$ to the power $3t$ and hence now you put this x_t inverse here in this okay. So you have x_t with you, this is x_t then x_s inverse.

So when X_s inverse will be $2/7 e$ to the power $-s/2$ $1/7 e$ to the power $-s/2$ $-1/7 e$ to the power $3s$ $13/7 e$ to the power $3s$ so put here an f_s , f_s is given to us as e to the power $2s$, e to the power $-s$. So we put the value of f_s thus inside this then we have to integrate with respect to s . Remember this t and s are independent variables so X_t you can even write outside the integral okay.

We just need to find the product of X_s inverse and f_s and then integrate with respect to s and then multiply ultimately by the X_t matrix that is the fundamental matrix this one. So after these competitions what you get is x_{pt} = this matrix $1/7$ 3 to the power $2t$ $-5/4 e$ to the power $-t$ $10/3 e$ to the power $2t$ $-13/6 e$ to the power $-t$.

(Refer Slide Time: 25:50)

Now using, $x(t) = x_c(t) + x_p(t)$, and $x(0) = [4 \ -1]^T$, we have

$$x(t) = \begin{bmatrix} \frac{19}{7} e^{t/2} + \frac{29}{28} e^{3t} + \frac{3}{7} e^{2t} - \frac{5}{28} e^{-t} \\ \frac{19}{21} e^{t/2} - \frac{29}{14} e^{3t} + \frac{10}{21} e^{2t} - \frac{13}{42} e^{-t} \end{bmatrix}$$

$x(t) = x_c(t) + x_p(t) = \begin{bmatrix} 3c_1 e^{t/2} - c_2 e^{3t} \\ c_1 e^{t/2} + 2c_2 e^{3t} \end{bmatrix} + \begin{bmatrix} \frac{3}{7} e^{2t} - \frac{5}{28} e^{-t} \\ \frac{10}{21} e^{2t} - \frac{13}{42} e^{-t} \end{bmatrix}$

$= \begin{bmatrix} c_1 e^{t/2} + c_2 e^{3t} + \frac{3}{7} e^{2t} - \frac{5}{28} e^{-t} \\ c_1 e^{t/2} + 2c_2 e^{3t} + \frac{10}{21} e^{2t} - \frac{13}{42} e^{-t} \end{bmatrix}$

$x(0) = \begin{bmatrix} 3c_1 - c_2 + \frac{3}{7} - \frac{5}{28} \\ c_1 + 2c_2 + \frac{10}{21} - \frac{13}{42} \end{bmatrix} = \begin{bmatrix} 4 \\ -1 \end{bmatrix}$

$c_1 = \frac{19}{21}, c_2 = -\frac{29}{28}$

So we can write general solution $x_t = x_{ct} + x_{pt}$ gives us now let us see x_{ct} is what this is $3c_1 e$ to the power $t/2$ $-c_2 e$ to the power $3t$ and then we have $c_1 e$ to the power $t/2$ $+ 2c_2 e$ to the

power $3t$ and to this we add this matrix, $\frac{3}{7} e$ to the power $2t$ then we have $\frac{10}{21} e$ to the power $2t$ and then we have $-\frac{5}{28} e$ to the power $-t$ and then we have $-\frac{13}{42} e$ to the power $-t$, okay, so we add the 2 matrix.

We add the 2 matrix $x(t)$ okay, $x(t)$ is this and $x'(t)$ is this, okay, we get then $3c_1 e$ to the power $t/2 - c_2 e$ to the power $3t + \frac{3}{7}$ we add component wise, e to the power $2t - \frac{5}{28} e$ to the power $-t$ and then $c_1 e$ to the power $t/2 + 2c_2 e$ to the power $3t$ and then we get $\frac{10}{21} e$ to the power $2t$ and then $-\frac{13}{42} e$ to the power $-t$.

So this is the general solution of $dx/dt = Ax + f(t)$, this is the general solution of this. Now let us apply the initial condition. So we put $t = 0$ in this and so $x(0)$ will be = put $t = 0$ here, $3c_1 - c_2 + \frac{3}{7} - \frac{5}{28}$ and here we get $c_1 + 2c_2$ and $\frac{10}{21}$ and we get $-\frac{13}{42}$ this is = we are given $4 - 1$. So this will give you 2 equations, $3c_1 - c_2 + \frac{3}{7} - \frac{5}{28} = 4$ $c_1 + 2c_2 + \frac{10}{21} - \frac{13}{42} = -1$ so these are 2 linear equations in 2 unknowns c_1 and c_2 we can determine the value of c_1 and c_2 here.

And then put in the general solution okay, so c_1 and c_2 we can put here and when you put the values of c_1 and c_2 you arrive at this solution, so $x(t) = \frac{19}{7} e$ to the power, so you can see here the coefficient of e to the power $t/2$ is $\frac{19}{7}$ that means $3c_1 = \frac{19}{7}$ so c_1 will come out to be $\frac{19}{21}$ when you find $c_1 =$ this and the coefficient of e to the power $3t$ is $-c_2 - c_2$ is $\frac{29}{28}$ so c_2 will come out to be $-\frac{29}{28}$.

So put these values okay, of c_1 c_2 here in this general solution you get the solution of the initial value problem.

(Refer Slide Time: 30:09)

Solution formula using matrix exponential: The solution formula for (1) using the fundamental matrix $X(t)$ is given by

$$x(t) = cX(t) + \int X(t)\{X(s)\}^{-1}f(s)ds.$$

Now using $e^{At} = X(t)X^{-1}(0)$,
the solution of IVP (5) is given by

$$x(t) = e^{A(t-t_0)}x_0 + \int_{t_0}^t e^{A(t-s)}f(s)ds. \quad (6)$$

Using the formula (6) we can find the solution of example (1).

$$x(t) = c e^{At} X(0) + \int_0^t e^{A(t-s)} X(0)^{-1} e^{As} f(s) ds$$

$$= c e^{At} + \int_0^t e^{A(t-s)} f(s) ds$$

$$e^{As} = X(s) X^{-1}(0)$$

$$(X(s))^{-1} e^{As} = X^{-1}(0)$$

$$x_0 = c e^{At_0} + \int_{t_0}^t e^{A(t-s)} f(s) ds$$

Now the solution formula for the nonhomogeneous system okay, the solution formula for the nonhomogeneous system $\dot{x} = Ax + ft$ using the fundamental matrix we know is given by this okay, now let us apply we will find the another formula, alternate formula for the matrix solution e to the power At we know e to the power At is $Xt * X^{-1}(0)$ so if you put here the value of Xt we get this following.

$Xt = e$ to the power $At * x_0$ okay, x_0 inverse, x_0 will be e to the power $As = x_0 * x^{-1}(0)$. Now we want to find x_0 inverse so premultiply by x_0 inverse, so x_0 inverse e to the power $As = x^{-1}(0)$ okay.

And x_0 inverse is therefore = post multiply by e to the power $-s$, so we get $x^{-1}(0) e$ to the power $-As$. So let us put here so $x^{-1}(0) * e$ to the power $-As$ ds and we arrive at, now $c * x_0$, where 0 is a constant, c is a constant so we can put another constant c dash, e to the power $At + x_0 * x^{-1}(0)$ is identity matrix so e to the power $At * e$ to the power $-As$ is e to the power A times $t-s$ ds .

Okay, so this is the formula and when you have to use $x(t) \neq x$ not then to determine this c dash okay, what you do put here that value so $x(t) \neq x$ not, $x \neq c$ dash, e to the power At_0 and here you get the integral okay, t_0 to t , okay, x not when we put $t = t_0$ okay yeah this integral will be 0 so $Xt = X_0 = c$ dash $A t_0$ and therefore c dash = x not $* e$ to the power $-A t_0$.

So you put here c dash = x not * e to the power -A t0 so we will get e to the power A times t - t0 * x not + this integral. You can put here t = t0 this integral vanishes and what we get is x t ! = x not. Now this formula we can also use to determine the solution of example 1 okay, particular solution of example 1, here we need to find the matrix e to the power At.

E to the power At can then be found by xt * x inverse 0 now to determine x inverse 0 what you do, you have the matrix xt with you, put t = 0 in that you will have x0 3/3 matrix X0 find the inverse of the matrix you will have x inverse 0. So then we will take the product of Xt with x inverse 0 to determine e to the power At and put here in this formula will get the solution. Now there is one more method, solution method by decoupling.

(Refer Slide Time: 34:17)

Solution method by decoupling: If A is diagonalizable i.e. $A = PDP^{-1}$, then the system (4) can be decoupled by setting $x(t) = Pu(t)$.

The system for u(t) becomes

$$\frac{du}{dt} = Du(t) + P^{-1}f(t).$$

$$P = [u_1 \ u_2 \ \dots \ u_n]$$

$$P^{-1} = \begin{bmatrix} \lambda_1 & & 0 \\ & \lambda_2 & \\ 0 & & \lambda_n \end{bmatrix}$$

$$\frac{dx}{dt} = Ax + f(t)$$

$$P \frac{du}{dt} = (PDP^{-1})P(u(t)) + f(t)$$

$$\frac{dx}{dt} = P \frac{du}{dt}$$

$$P \frac{du}{dt} = PDu(t) + f(t)$$

$$\frac{du}{dt} = Du(t) + P^{-1}f(t)$$

If A is diagonalizable we know that they are just non-singular matrix P such that $A = PDP^{-1}$ and then the system 4, okay, $dx/dt = Ax + ft$ can be expressed like this. If you assume $x = Pu$, suppose you assume $x = Pu$ then dx/dt where P is this matrix, so Pdu/dt so what you get $Pdu/dt = A is PDP^{-1} * x is Pu + ft$, okay so $Pdu/dt = now P^{-1}P$ is the identity matrix so you get $PDu + ft$.

Now pre-multiply this equation by P^{-1} . So $P^{-1}P$ will be identity matrix and we will get $du/dt = Du + P^{-1}ft$. So this is how we get this formula okay, so if the matrix A is diagonalizable okay, then we can use this formula also. We will solve this equation we know the matrix P with P^{-1} is the matrix which is found from the eigen vectors of A okay, so we find the matrix P from the eigen vectors of A.

Let us say they are v_1, v_2, v_n since they are linearly independent we will be able to find P inverse also okay. D matrix will support v_1 eigen vector corresponding to λ_1, v_2 eigen vector corresponding to λ_2 and v_n eigen vector corresponding to λ_n then this is your D matrix, okay. So we have $A = PDP^{-1}$. We know the D matrix we know D matrix P inverse because we know P .

We can substitute in this and determine solve this equation. Okay, let us see for example 1, in the case of example 1 we have seen the eigen vectors corresponding to $\lambda = 1/2, 3$ are 31-12.

(Refer Slide Time: 36:32)

For the example 1, we have

$$P = \begin{bmatrix} 3 & -1 \\ 1 & 2 \end{bmatrix} \text{ and } D = \begin{bmatrix} \frac{1}{2} & 0 \\ 0 & 3 \end{bmatrix}$$

Now let $x(t) = Pu(t)$

Then the system for $u(t)$ is given by

$$\frac{du}{dt} = Du(t) + P^{-1}f(t),$$

where

$$P^{-1} = \frac{1}{7} \begin{bmatrix} 2 & 1 \\ -1 & 3 \end{bmatrix}$$

So this is your P matrix, D matrix is $\lambda_1 = 1/2, \lambda_2 = 3$ so this is D matrix $x(t) = Pu(t)$ let us assume, so then $du/dt = Du(t) + P^{-1}f(t)$. P inverse if you find for this matrix P it comes out to be this matrix $2/7, 1/7, -1/7$ and $3/7$ okay. We know the matrix D now okay. We know the matrix P inverse and so we can find P inverse $f(t)$, $f(t)$ is also know to us. Okay.

(Refer Slide Time: 37:15)

For the example 1, we have

$$P = \begin{bmatrix} 3 & -1 \\ 1 & 2 \end{bmatrix} \text{ and } D = \begin{bmatrix} \frac{1}{2} & 0 \\ 0 & 3 \end{bmatrix}$$

$$\frac{du}{dt} + Pu = Q$$

Now let $x(t) = Pu(t)$

Then the system for $u(t)$ is given by

$$\frac{du}{dt} = Du(t) + P^{-1}f(t),$$

where

$$P^{-1} = \frac{1}{7} \begin{bmatrix} 2 & 1 \\ -1 & 3 \end{bmatrix}$$

$$u(t) = \begin{bmatrix} u_1(t) \\ u_2(t) \end{bmatrix}$$

$$\begin{bmatrix} \frac{du_1}{dt} \\ \frac{du_2}{dt} \end{bmatrix} = \begin{bmatrix} \frac{1}{2} & 0 \\ 0 & 3 \end{bmatrix} \begin{bmatrix} u_1(t) \\ u_2(t) \end{bmatrix} + \begin{bmatrix} \alpha(t) \\ \beta(t) \end{bmatrix}$$

$$\frac{du_1}{dt} = \frac{1}{2}u_1(t) + \alpha(t)$$

$$\frac{du_2}{dt} = 3u_2(t) + \beta(t)$$

So now what will happen, du/dt is let us say $U_t = U_1t U_2t$ okay, so then du/dt will be du_1/dt or du_2/dt , this is du/dt . D is your matrix, $1/20$ and 03 , okay. U_2 is u is $u_1t u_2t$ then you know P inverse * $f(t)$ which is again a column matrix, okay, you will have $du_1/dt =$ you can multiply here $1/2u_1t +$ let us say p inverse $f(t)$ is $\alpha t \beta t$. So you will get $+$ αt this is one equation and the similarly second equation is $du/dt = 3u_2t + \beta t$.

Now this equation and this equation they are linear equations in u_1 okay. We know how to solve the equation $dy/dx + Py = Q$ where P and Q are functions of x . so you can solve $du_1/dt - 1/2 U_1 = \alpha t$ from this and $Dut/dt - 3 ut = \beta t$ also from this we can find the integrating factor and then find the solution u_1t and u_2t . So we will find that.

(Refer Slide Time: 39:02)

which implies

$$u_1'(t) = \frac{1}{2}u_1 + \frac{2}{7}e^{2t} + \frac{1}{7}e^{-t}, \text{ and}$$

$$u_2'(t) = 3u_2 - \frac{1}{7}e^{2t} + \frac{2}{7}e^{-t}$$

Now, $x(0) = Pu(0)$

$$\Rightarrow u(0) = \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

$$u_1(0) = 1$$

$$u_2(0) = -1$$

So these are the equations for u_1 and u_2 differential equations when you solve them you get the values of $u_1(t)$ and $u_2(t)$ and then you apply this initial condition. Initial condition we have assumed that $x(t) = Pu(t)$, so $x(0) = Pu(0)$ and then $u(0) = P^{-1}x(0)$. $P^{-1}x(0)$ if you find okay, you will get $\begin{bmatrix} 1 \\ -1 \end{bmatrix}$, so $u_1(0) = 1$ and $u_2(0) = -1$. So we have these 2 linear equations in u_1 and u_2 with the initial conditions $u_1(0) = 1$ $u_2(0) = -1$. We can solve them easily to get the value of $u_1(t)$ and $u_2(t)$.

(Refer Slide Time: 39:48)

$$\text{Hence } u_1(t) = \frac{19}{21}e^{t/2} + \frac{4}{21}e^{2t} - \frac{2}{21}e^{-t}, \quad \text{and}$$

$$u_2(t) = -\frac{29}{28}e^{3t} + \frac{1}{7}e^{2t} - \frac{3}{28}e^{-t}.$$

Finally solution of original problem is given by

$$x(t) = Pu(t) = \begin{bmatrix} \frac{19}{7}e^{t/2} + \frac{29}{28}e^{3t} + \frac{3}{7}e^{2t} - \frac{5}{28}e^{-t} \\ \frac{19}{21}e^{t/2} - \frac{29}{14}e^{3t} + \frac{10}{21}e^{2t} - \frac{13}{42}e^{-t} \end{bmatrix}.$$

Now we know the vector $u(t)$ so $x(t)$ will be $P \cdot u(t)$ okay. So multiply this vector $u(t)$ whose components are $u_1(t)$ and $u_2(t)$ by the matrix P will get the solution of the example 1. So this is another method which we use in case the matrix A is diagonalizable. So with that I come to the end of my lecture. Thank you very much for your attention.
