Lecture - 33
Initial Value Problem for Quasi-Linear First Order Equations

Hello friends. Welcome to my lecture on initial value problem for quasi-linear first order equations.

(Refer Slide Time: 00:32)

We know that first order quasi-linear PDE is of the form

$$P(x, y, z) \frac{\partial z}{\partial x} + Q(x, y, z) \frac{\partial z}{\partial y} = R(x, y, z) \quad (1)$$

Assume that an initial surface or a possible solution surface $z = z(x, y)$ of (1) can be found.

Then, $F(x, y, z) = z(x, y) - z = 0$

$\Rightarrow \frac{\partial F}{\partial x} = \frac{\partial z}{\partial x}, \frac{\partial F}{\partial y} = \frac{\partial z}{\partial y}$ and $\frac{\partial F}{\partial z} = -1$

Since the gradient vector $\nabla F = (z_x, z_y, -1)$ is normal to integral surface $F(x, y, z) = 0$, the equation (1) yields us

We know that a first order quasi-linear partial differential equation is of the form $P(x, y, z) \frac{\partial z}{\partial x} + Q(x, y, z) \frac{\partial z}{\partial y} = R(x, y, z)$. Now let us assume that an initial surface or a possible solution surface $z = z(x, y)$ of the equation 1 can be found.

Then, we can write this equation $z = z(x, y)$ as $z(x, y) - z = 0$, let us write $z(x, y) - z$ as a function of x, y, z . So $F(x, y, z) = z(x, y) - z = 0$ then the partial derivatives of F with respect to x, y and z can be determined, partial derivative of F with respect to x is derivative of z with respect to x , partial derivative of F with respect to y is partial derivative of z with respect to y and partial derivative of F with respect to z is -1 .

Now we know that $F(x, y, z) = 0$ represents a surface and ∇F is a vector which is normal to the surface. So here the components of ∇F which are the partial derivatives of F with

respect to x, y, z are z_x, z_y and -1 , so the gradient vector $\nabla F = z_x, z_y, -1$ is normal to the integral surface $F(x, y, z) = 0$. The equation 1 can be written as $P(x, y, z); Q(x, y, z); R(x, y, z)$ dot $z_x, z_y, -1 = 0$.

Let us take the dot product of the vectors $P(x, y, z); Q(x, y, z); R(x, y, z)$ with $z_x, z_y, -1 = 0$ then what we get is this equation.

(Refer Slide Time: 02:37)

$$(P(x, y, z), Q(x, y, z), R(x, y, z)) \cdot (z_x, z_y, -1) = 0$$
 i.e. the vector $(P(x, y, z), Q(x, y, z), R(x, y, z))$ and the gradient vector ∇F are orthogonal. Hence the vector

$$(P(x, y, z), Q(x, y, z), R(x, y, z))$$
 lies in the tangent plane of the surface $z = z(x, y)$ at each point (x, y) where $\nabla F \neq 0$.

The direction determined by the vector (P, Q, R) at each point (x, y, z) is known as characteristic direction. A curve in (x, y, z) -space, whose tangent at every point coincides with the characteristic direction field (P, Q, R) , is called a characteristic curve. Let the parametric equations of this curve be

$$x = x(t), y = y(t), z = z(t)$$

IIT KOOBEE NPTEL ONLINE CERTIFICATION COURSE 3

So what do we obtain, the vector $P(x, y, z); Q(x, y, z); R(x, y, z)$ is orthogonal to the vector $z_x, z_y, -1$ but $z_x, z_y, -1$ is a vector along the normal to the surface $F(x, y, z) = 0$ so the vector $P(x, y, z); Q(x, y, z); R(x, y, z)$ is a vector which lies in the tangent plane to the surface $z = z(x, y)$ at each point x, y where gradient of F is not 0. Now the direction determined by the vector P, Q, R that is $P(x, y, z); Q(x, y, z); R(x, y, z)$ which we are writing in short as P, Q, R .

The direction determined by the vector $P(x, y, z); Q(x, y, z); R(x, y, z)$ at each point x, y, z is known as the characteristic direction. A curve in x, y, z space whose tangent at every point coincides with the characteristic direction field P, Q, R is called as a characteristic curve. At each point of this characteristic curve, the tangent coincides with the characteristic direction that is the direction given by the vector P, Q, R .

Now the parametric equations of this characteristic curve let be $x = x(t), y = y(t), z = z(t)$. Then, the tangent vector to this curve we know if the curve in the space is given by $x = x(t), y = y(t), z = z(t)$.

(Refer Slide Time: 04:00)

then the tangent vector to this curve is $\left(\frac{dx}{dt}, \frac{dy}{dt}, \frac{dz}{dt}\right)$ hence

$$\frac{dx}{dt} = P(x, y, z), \quad \frac{dy}{dt} = Q(x, y, z), \quad \frac{dz}{dt} = R(x, y, z). \quad (2)$$

These equations are called the characteristic equations of (1) and the solutions of (2) are the characteristic curves of (1).

Assuming that P, Q, R are sufficiently smooth and do not all vanish at the same point, from the theory of ODE, a unique characteristic curve passes through each point (x_0, y_0, z_0) . To solve the IVP for (1), we pass a characteristic curve through each point of initial curve C given by IVP. These curves generate an integral surface which is the solution of the IVP.

Then, the tangent vector to this curve be given by $dx/dt, dy/dt, dz/dt$ and therefore dx/dt will be $=P(x, y, z); dy/dt=Q(x, y, z); dz/dt=R(x, y, z)$ because of this because this curve is a characteristic curve. So at each point of this curve the tangent to this curve will coincide with the characteristic direction and so dx/dt will be $P(x, y, z); dy/dt$ will be $Q(x, y, z); dz/dt$ will be $R(x, y, z)$. These equations are called as the characteristic equations of the quasi-linear PDE.

And the solutions of 2 are called the characteristic curves of 1, so the solutions of this equation $dx/dt=P(x, y, z); dy/dt=Q(x, y, z); dz/dt=R(x, y, z)$ are called the characteristic curves of the quasi-linear PDE. Now assuming that P, Q, R are sufficiently smooth and do not all vanish at the same point then from the theory of ordinary differential equation a unique characteristic curve passes through each point x_0, y_0, z_0 .

So this is to be noted if P, Q, R are not of I mean do not vanish at the same point then a unique characteristic curve passes through each point x_0, y_0, z_0 . Now to solve the initial value problem for the quasi-linear PDE we pass a characteristic curve through each point of the initial curve C given by the IVP. In the initial value problem, you will be given an initial curve at $t=0$.

So to solve the initial value problem, we will have to pass the characteristic curve through each point of the curve C. These curves generate an integral surface which is the solution of the IVP.

(Refer Slide Time: 06:17)

In the non-parametric form, we may write (2) as

$$\frac{dx}{P} = \frac{dy}{Q} = \frac{dz}{R}$$

$$Pp + Qq = R$$

Method of characteristics or the method of Lagrange:

Theorem: The general solution of the quasi-linear PDE is

$$\phi(u, v) = 0 \quad (3)$$

where ϕ is an arbitrary function and $u(x, y, z) = a$ and $v(x, y, z) = b$ form a solution of the equations

$$\frac{dx}{P} = \frac{dy}{Q} = \frac{dz}{R} \quad (4)$$

In the non-parametric form, we can write the equation 2 as $dx/P=dy/Q=dz/R$. Now let us look at the method of characteristics or the method of Lagrange. So the general solution of the quasi-linear PDE is the theorem says that the general solution of the quasi-linear PDE $Pp+Qq=R$ where $P, Q,$ and R they are functions of x, y, z .

So the general solution of this quasi-linear PDE is $\phi u, v=0$ where ϕ is an arbitrary function and $u x, y, z=some\ constant\ a$ and $v x, y, z=some\ constant\ b$ they form a solution of the characteristic equations in the non-parametric that is $dx/P, dy/Q, dz/R$. Now let us prove this theorem. So we have to prove that the general solution of the quasi-linear PDE is given by $\phi u, v=0$ if $u x, y, z=a, v x, y, z=b$ form a solution of the characteristic equations $dx/P=dy/Q=dz/R$ and ϕ is an arbitrary function.

(Refer Slide Time: 07:40)

Proof: If $u(x, y, z) = a$ and $v(x, y, z) = b$ satisfy (1) then

$$u_x dx + u_y dy + u_z dz = 0$$

and

$$v_x dx + v_y dy + v_z dz = 0$$

must be compatible with (4) which implies

$$Pu_x + Qu_y + Ru_z = 0 \quad \checkmark$$

$$Pv_x + Qv_y + Rv_z = 0 \quad \checkmark$$

Solving for P, Q and R , we get

$$\frac{P}{u_y v_z - u_z v_y} = \frac{Q}{u_z v_x - u_x v_z} = \frac{R}{u_x v_y - u_y v_x} \quad \text{or} \quad \frac{P}{\frac{\partial(u,v)}{\partial(y,z)}} = \frac{Q}{\frac{\partial(u,v)}{\partial(z,x)}} = \frac{R}{\frac{\partial(u,v)}{\partial(x,y)}}$$

So let us see how we prove this, so if $u(x, y, z) = \text{some constant } a$ and $v(x, y, z) = \text{some constant } b$ they satisfy the quasi-linear PDE that is $Pp + Qq = R$ then from $u(x, y, z) = a$ we see that the partial derivative of u with respect to x that is $u_x dx +$ partial derivative of u with respect to y that is $u_y dy +$ partial derivative of u with respect to z that is $u_z dz$ is 0. Similarly, $v(x, y, z) = b$ gives you partial derivative of v with respect to $x dx +$ partial derivative of v with respect to $y dy +$ partial derivative of v with respect to $z dz = 0$.

Now these equations must be compatible with (4) this characteristic equation because $u(x, y, z) = a$ and $v(x, y, z) = b$ form a solution of this characteristic equation so they must be compatible with (4) which implies that now (4) gives what (4) is $dx/P = dy/Q = dz/R$ okay so if these equations are compatible with this equation then what we will have $P du_x + Q du_y + R du_z = 0$ and then $P v_x + Q v_y + R v_z = 0$.

Now we solve these two equations this and this for $P, Q,$ and R what we will get $P/u_y v_z - u_z v_y = Q/u_z v_x - u_x v_z$ and then $R/u_x v_y - u_y v_x$. So this is what we get when we solve these two equations for P, Q and R . Now we can write them in the form of the Jacobian. This gives you $P/\text{Jacobian of } u, v \text{ with respect to } y, z$ okay and then we will get the Jacobian of here u, v again with respect to z and x .

And we get here Jacobian of u, v with respect to x, y okay. So we can write these ratios in the form of Jacobian $P/\Delta u, v/\Delta y, z$ and then $\Delta u, v/\Delta z, x$ and then $\Delta u, v/\Delta x, y$.

(Refer Slide Time: 10:36)

$$\text{or } \frac{P}{\frac{\partial(u, v)}{\partial(y, z)}} = \frac{Q}{\frac{\partial(u, v)}{\partial(z, x)}} = \frac{R}{\frac{\partial(u, v)}{\partial(x, y)}} \quad (5)$$

Differentiating (3), partially with respect to x and y we have

$$\frac{\partial \phi}{\partial u} \left\{ \frac{\partial u}{\partial x} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial x} \right\} + \frac{\partial \phi}{\partial v} \left\{ \frac{\partial v}{\partial x} + \frac{\partial v}{\partial z} \frac{\partial z}{\partial x} \right\} = 0$$

$$\frac{\partial \phi}{\partial u} \left\{ \frac{\partial u}{\partial y} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial y} \right\} + \frac{\partial \phi}{\partial v} \left\{ \frac{\partial v}{\partial y} + \frac{\partial v}{\partial z} \frac{\partial z}{\partial y} \right\} = 0.$$

$$\phi(u, v) = 0$$

$$u = u(x, y, z) = c_1$$

$$v = v(x, y, z) = c_2$$

So we get this now differentiating 3. Let us differentiate 3, 3 is it is phi u, v=0 so let us see when we differentiate phi u, v=0 where u=u x, y, z and v= v x, y, z; u x, y, z=c1 and v x, y, z=c2. So when we differentiate this equation phi u, v=0 partially with respect to x what we get phi u*ux+uz*zx+phi v*vx+vz*zx=0 and similarly when we differentiate it with respect to y we get phi u*uy+uz*q+phi v*vy+vz*q=0. So this is what we get when we differentiate phi u, v=0 with respect to x and y.

(Refer Slide Time: 11:48)

Eliminating $\frac{\partial \phi}{\partial u}$ and $\frac{\partial \phi}{\partial v}$, we get

$$\begin{vmatrix} \frac{\partial u}{\partial x} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial x} & \frac{\partial v}{\partial x} + \frac{\partial v}{\partial z} \frac{\partial z}{\partial x} \\ \frac{\partial u}{\partial y} + \frac{\partial u}{\partial z} \frac{\partial z}{\partial y} & \frac{\partial v}{\partial y} + \frac{\partial v}{\partial z} \frac{\partial z}{\partial y} \end{vmatrix} = 0$$

or
$$p \left(\frac{\partial u}{\partial y} \frac{\partial v}{\partial z} - \frac{\partial v}{\partial y} \frac{\partial u}{\partial z} \right) + q \left(\frac{\partial u}{\partial z} \frac{\partial v}{\partial x} - \frac{\partial v}{\partial z} \frac{\partial u}{\partial x} \right) = \left(\frac{\partial u}{\partial x} \frac{\partial v}{\partial y} - \frac{\partial v}{\partial x} \frac{\partial u}{\partial y} \right)$$

or
$$p \frac{\partial(u, v)}{\partial(y, z)} + q \frac{\partial(u, v)}{\partial(z, x)} = \frac{\partial(u, v)}{\partial(x, y)}$$

or
$$Pp + Qq = R, \text{ in view of (5).}$$

And then when we eliminate phi u and phi v from these two equations what we will get, we will get the determinant of ux+uz*p uy+uz*q and vx+vz*p vy+vz*q=0. So this determinant will be equal to 0 and when we solve this determinant we get this equal to 0 so when we put p for zx and q for zy and solve okay simplify this equation, we get p times uy vz-vy uz+q times ux vx-vz ux and then ux vy-vx uy and which we can write in the form of Jacobian as p*del u, v/del y, z+q del u, v/del z, x=del u, v/del x, y.

And then we can see in view of 5 this equation okay, let us use this equation 4 then what do we notice this equation will be replaced by Pp+Qq=R in view of 5.

(Refer Slide Time: 13:27)

Thus, (3) is solution of (1).

Example: Let us consider $xz_x + yz_y = z$.

Then the general solution is

$$f\left(\frac{x}{y}, \frac{y}{z}\right) = 0$$

The general solution is $\phi(u, v) = 0$
 $\phi\left(\frac{x}{y}, \frac{y}{z}\right) = 0$

9

So we see that $\phi(u, v) = 0$ is the solution of equation 1 if $u = x/y, z = \text{constant}$ and $v = y/z, x = \text{constant}$ satisfy the characteristic equations. Now let us look at this equation $xz_x + yz_y = z$. So this is of the form $xp + yq = z$. So it is quasi-linear first order PDE, so we can write the characteristic equations $dx/x = dy/y = dz/z$. Now solving the relation dx/x , there are two independent relations.

So $dx/x = dy/y$ gives us $\ln x = \ln y + \ln c_1$, so we get $x/y = c_1$ so this is one solution. We can take another independent relation $dy/y = dz/z$ which gives us $\ln y = \ln z + \ln c_2$ and we can write $y/z = c_2$ so we get this is your $u = x/y, z = \text{constant}$ and this is our $v = y/z, x = \text{constant}$. So we got two solutions $u = x/y, z = \text{constant}$, $v = y/z, x = \text{constant}$ which are the solutions of the characteristic equation $dx/x = dy/y = dz/z$.

Hence, the general solution is given by $\phi(u, v) = 0$. So that means $\phi(x/y, y/z) = 0$. We can instead of taking $dy/y = dz/z$ one can take the $dx/x = dz/z$ also. So there are two independent relations, third one is dependent on the other two. So we can write the general solution of this quasi-linear PDE as an arbitrary function ϕ of $x/y, y/z = 0$ here we have written f instead of ϕ .

(Refer Slide Time: 16:03)

Example: Let us consider $z(x+y)z_x + z(x-y)z_y = x^2 + y^2$. Then the general solution is $f(2xy - z^2, x^2 - y^2 - z^2) = 0$.

The characteristic equations are $\frac{dx}{z(x+y)} = \frac{dy}{z(x-y)} = \frac{dz}{x^2+y^2}$. To find another solution, we notice that $x dx - y dy - z dz = \frac{1}{2} d(x^2 - y^2 - z^2)$.

From (1) and (2), we get $2xy + c = z^2 = a$ or $2xy - z^2 = a - c = b$. Then, the general solution is $f(u, v) = 0$ or $f(2xy - z^2, x^2 - y^2 - z^2) = 0$. Hence, $x dx - y dy - z dz = 0 \Rightarrow \frac{x^2}{2} - \frac{y^2}{2} - \frac{z^2}{2} = \beta \Rightarrow x^2 - y^2 - z^2 = 2\beta = a$. $u = x^2 - y^2 - z^2, v = 2xy - z^2$.

NPTEL ONLINE CERTIFICATION COURSE 10

Now let us go to another problem, so we have a quasi-linear PDE of first order. Let us compare this given partial differential equation with the standard form $Pp+Qq=R$ then $P=z*x+y$ or $Q=z*x-y$, $R=x$ square+y square. The characteristic equations are dx/P that is $z*x+y=dy/Q$ that is $z*x-y$ and we have dz/R which is x square+y square. Now let us first consider dx/z times $x+y=dy/z$ times $x-y$.

Then, we can write it as $x-y*dx=x+y dy$ or I can write it as $x dx-y dy=x dy+y dx$. Integrating both sides I have x square/2-y square/2= xy +some constant say alpha okay or I can write x square-y square= $2xy$ +some constant+2 alpha which I can write as $2xy$ +some constant c where c is 2 alpha okay so one solution we have found x square-y square- $2xy$ =constant. Let us find another solution.

So we notice that $x dx-y dy-z dz$ if you consider then this is $x*z$ $x+y-yz*x-y-z$ times x square+y square okay. So these ratios are equal to this, the characteristic equations are $dx/P, dy/Q, dz/R$ which is also equal to this, so this is equal to $x dx-y dy-z dz/x$ square $z+xyz-xyz+y$ square $z-x$ square $z-y$ square z . So x square z cancel, y square z also cancels and xyz xyz cancel so this implies that $x dx-y dy-dz dz/0$ okay.

So this equal to this and this implies that hence $x dx-y dy-z dz=0$ when we integrate this we get x square/2-y square/2-z square/2=some constant let us say beta okay. So this gives you x square-y square-z square= 2 beta which we can take as say a okay. So x square-y square-z square is=a, the other solution we have got x square-y square= $2xy+c$. So I can also write this solution this one okay this solution.

I can also write as $x^2 - y^2 - 2xy = c$ okay. Now from this solution let us say this is 1, this is 2 so from 1 and 2, if we write $x^2 - y^2 = 2xy + c$ then what we get from 1 and 2. I get $2xy + c - z^2 = a$ or I can say $2xy - z^2 = a - c$ which I can write as another constant b okay. So one solution is $x^2 - y^2 - z^2 = u$ and the other solution we can take as $2xy - z^2 = b$.

So then the general solution is $f(u, v) = 0$ say u is $x^2 - y^2 - z^2$ and v we can take as $2xy - z^2$. So I can write $f(u, v) = 0$ or I can write as $f(v, u) = 0$. So we get the solution as f of $2xy - z^2$ and then $x^2 - y^2 - z^2 = 0$ so this is how we get the general solution of this quasi-linear first order PDE.

(Refer Slide Time: 23:24)

Example: Let us consider

$$px(z - 2y^2) + qy(z - y^2 - 2x^3) = z(z - y^2 - 2x^3).$$

$\lambda dx + \mu dy + \nu dz = 0$
 $\lambda = 1, \mu = 2y, \nu = -2$
 $1 \cdot x(z - 2y^2) + 2y^2(z - y^2 - 2x^3) - 2z(z - y^2 - 2x^3) = 0$

$\frac{dx}{x(z - 2y^2)} = \frac{dy}{y(z - y^2 - 2x^3)} = \frac{dz}{z(z - y^2 - 2x^3)}$
 $\frac{dy}{y} = \frac{dz}{z} \Rightarrow \ln y = \ln z + \ln c_1$
 $\Rightarrow \frac{y}{z} = c_1$
 $u(x, y, z) = \frac{y}{z} = c_1$

$\frac{dx}{x} = \frac{dz}{z} \Rightarrow \ln x = \ln z + \ln c_2$
 $\Rightarrow \frac{x}{z} = c_2$
 $v(x, y, z) = \frac{x}{z} = c_2$

$\frac{dx}{x} = \frac{2y dy - dz}{2y^2(z - y^2 - 2x^3) - z(z - y^2 - 2x^3)}$
 $\frac{dx}{x} = \frac{2y dy - dz}{(2y^2 - z)(z - y^2 - 2x^3)}$
 $\frac{dx}{x} = \frac{dz - 2y dy}{z - y^2 - 2x^3} = \frac{dw}{w - 2x^3}$
 $w = z - y^2$
 $\frac{dw}{w - 2x^3} = \frac{dz - 2y dy}{z - y^2 - 2x^3}$

11

Now let us look at this equation. This is again a quasi-linear PDE of first order, so dx/x times $z - 2y^2 = dy/y \cdot z - y^2 - 2x^3$ and then $dz/z \cdot z - y^2 - 2x^3$. Now let us see these characteristic equations carefully. This second ratio dy/y times $z - y^2 - 2x^3 = dz/z \cdot z - y^2 - 2x^3$, if we take first this relation then we will easily be able to get the first solution. So dy/y times $z - y^2 - 2x^3 = dz/z \cdot z - y^2 - 2x^3$ okay.

So from this what we get this vector will cancel, we will get $dy/y = dz/z$ and this will give you $\ln y = \ln z + \ln c_1$. So we get one solution $y/z = c_1$, so one solution we have got, we can take it as u , $x, y, z = y/z = c_1$, so one solution we have got. Now let us look at the other solution. So we have to choose λ, μ, ν in such a way that $\lambda dx + \mu dy + \nu dz$ becomes 0. So what I do is I choose λ as say 1, μ as $2y$ and ν as -2 .

Then what I will get, so x times $z-2y$ square we are multiplying by 1 so this+mu we are choosing $2y$, so $2y$ by times this so $2y$ square $z-y$ square- $2x$ cube, what we have to do, what I will get $-2z*z-y$ square- $2x$ cube=0, will I get that 0? We should not try this. Let me see dx/x $z-2y$ square is=and here what we will take $2ydy-dz$ let us try this okay. So here we take $2y$ so $2y$ square* $z-y$ square- $2x$ cube- z times $z-y$ square- $2x$ cube, let us do this okay.

So this is what $2ydy-dz/2y$ square- z and what I will get $z-y$ square- $2x$ cube okay. So what I will do, this $z-2y$ square will cancel with $z-2y$ square, we will get dx/x =yeah $z-2y$ square will cancel with this $dz-2ydy/z-y$ square- $2x$ cube, we get this okay. Now let us take some $w=z-y$ square, then dw will be= $dz-2ydy$. So this will be= $dw/w-2x$ cube and let us solve this okay. So what I will get, dx/x = $dw/w-2x$ cube and what I get x dw = w $dx-2x$ cube dx which I can write as x $dw-w$ dx/x square=- $2x$ dx okay.

And this is d of w/x =- d of x square, so when we integrate we get w/x =- x square+ a constant c_2 okay and w is what $z-y$ square, so we get $z-y$ square/ x + x square= c_2 . So this is another solution. We can write it as u x , y , z =this. So what we get, one solution is this $y/z=c_1$ and the other solution is x square+ $zyx-y$ square/ x = c_2 .

(Refer Slide Time: 30:12)

Then the general integral is

$$\phi\left(\frac{y}{z}, x^2 + \frac{z}{x} - \frac{y^2}{x}\right) = 0.$$

12

And we therefore have this general solution, ϕ y/z , x square+ $z/x-y$ square/ x =0. So this is how we get the general integral for this equation.

(Refer Slide Time: 30:27)

Example: Find the equation of integral surface of the differential equation

$$2y(z-3)p + (2x-z)q = y(2x-3)$$

which passes through the circle

$$z = 0, x^2 + y^2 = 2x.$$

$$\frac{dx}{2y(z-3)} = \frac{dy}{2x-z} = \frac{dz}{y(2x-3)}$$

$$\frac{dx}{2y(z-3)} = \frac{dz}{y(2x-3)} \Rightarrow 2x dx - 3 dx = 2z dz - 6 dz$$

$$\Rightarrow x^2 - 3x = z^2 - 6z + c_1 \text{ or } x^2 - 3x - z^2 + 6z = c_1$$

Thus, $u(x, y, z) = x^2 - 3x - z^2 + 6z = c_1$ as one solution

$$\lambda dx + \mu dy + \nu dz = 0$$

Let $\lambda = 1, \mu = 2y, \nu = -2$

Then $\lambda dx + \mu dy + \nu dz = 0$

$$= 2y(z-3) + 4xy - 2yz - 4xy + 6y = 0$$

$$dx + 2y dy - 2dz = 0 \Rightarrow x + y^2 - 2z = c_2$$

$$v(x, y, z) = x + y^2 - 2z = c_2$$

$$\phi(u, v) = 0$$

Now let us look at last problem of this lecture. Find the equation of integral surface of the differential equation first order quasi-linear PDE $2y z-3 p+2x-z q=y$ times $2x-3$ which passes through the circle. So let us first solve this quasi-linear PDE. So we have the characteristic equations as $dx/2y$ times $z-3=dz/y$ times $2x-3$. So these are the characteristic equations for this quasi-linear first order PDE.

So you can see we take $dx/2yz-3$ and dz/y times $2x-3$ then y will cancel and we will be able to integrate easily. So $dx/2yz-3$ let us take dz/y times $2x-3$. Then this y will cancel with y and we shall get $2x dx-3 dx=2z dz-6 dz$ which gives us on integration we get x square- $3x$ then we get z square- $6z$ +constant c_1 or we can say x square- $3x-z$ square+ $6z=c_1$. So thus we have u $x, y, z=x$ square- $3x-z$ square+ $6z=c_1$ is one solution.

Now let us try to find the other solution. So for that let us again try λ, μ, ν such that $\lambda dx + \mu dy + \nu dz = 0$ where λ, μ, ν are functions of x, y, z . So what I will do is let us take $\lambda=1, \mu=2y$ and $\nu=-2$ let us see this. So what we will get, then $\lambda dx + \mu dy + \nu dz$, this will be giving you, we are multiplying by 1 so $2y z-3, \mu$ is $2y$ so $2y*2x-z$.

So we get $4xy-2yz$ and then ν is -2 so $-4xy+6y$ and we can see that this cancels with this and then here we get $2yz$ which will cancel with this $2yz$ and $-6y$ will cancel with $6y$, so we get 0 and thus $dx+2y dy-2dz=0$ which gives us on integration $x+y$ square- $2z=a$ constant c_2 . So we got another solution v $x, y, z=x+y$ square- $2z=c_2$ and therefore the general solution is $\phi(u, v)=0$.

(Refer Slide Time: 34:52)

Then the general solution is

$$\phi(x^2 - 3x - z^2 + 6z, x + y^2 - 2z) = 0$$

and the required integral surface is

$$x^2 + y^2 - z^2 - 2x + 4z = 0.$$

Handwritten notes on the slide:

$x^2 + y^2 = 2x, z=0$
 $(x-1)^2 + y^2 = 1, z=0$
 $x = 1 + \cos t, z=0$
 $y = \sin t, z=0$
 $u(x, y, z) = x^2 - 3x - z^2 + 6z = c_1$
 $v(x, y, z) = x + y^2 - 2z = c_2$
 $(1 + \cos t)^2 - 3(1 + \cos t) = c_1$
 $(1 + \cos t) + \sin^2 t = c_2$
 $\Rightarrow 1 + \cos^2 t + 2\cos t - 3 - 3\cos t = c_1$
 $1 + \cos^2 t - \cos t = c_1 + 2$
 $\Rightarrow \cos^2 t - \cos t = c_1 + 2$
 $c_1 + c_2 = 0$

So we can write the general solution as $\phi(x^2 - 3x - z^2 + 6z, x + y^2 - 2z) = 0$. Now let us find the integral surface which passes through the circle $z=0, x^2 + y^2 = 2x$. So the circle is given by $x^2 + y^2 = 2x, z=0$ and this equation can be written as $(x-1)^2 + y^2 = 1, z=0$. Now let us write the equations of the circle in the parametric form.

So I can write $x=1+\cos t$ and $y=\sin t$ and $z=t=0$ so $z=0$ we get. Now what we will get, we have two solutions $u(x, y, z) = x^2 - 3x - z^2 + 6z = c_1$ okay so this is c_1 and then $v(x, y, z) = x + y^2 - 2z = c_2$ okay. So we have to find the integral surface that passes through this curve. Then, let us use the parametric form of the curve that is the circle through which the general solution or the solution of this has to pass.

So $x^2 - 3x$ so $(1 + \cos t)^2 - 3(1 + \cos t)$ since z is 0 so we get 0 here, here also 0 so this is equal to c_1 and then we have $x = 1 + \cos t$ the second equation and then we get $1 + \sin^2 t$ and we get $z=0$ so this is equal to c_2 . Now let us square $1 + \cos t$ so this gives you $1 + \cos^2 t + 2\cos t - 3 - 3\cos t = c_1$ and here what we get $1 + \cos^2 t - \cos t = c_1 + 2$. So simplifying we get $\cos^2 t$, then we have here $-\cos t$ and then $(\cos^2 t - \cos t) = c_1 + 2$ so we get $c_1 + 2$ and here we get $\cos t - \cos^2 t = c_2 - 2$.

So adding these two equations, this equation and this equation what do you notice, $\cos^2 t$ will cancel with $\cos^2 t$, $\cos t$ will cancel with $\cos t$, 2 will cancel with 2 and we will get $c_1 + c_2 = 0$ okay. So $c_1 + c_2 = 0$, if eliminating c_1, c_2 what we get, $x^2 - 3x - z^2 + 6z$

that is c_1 and c_2 is $x^2 + y^2 - 2z = 0$ okay $c_1 + c_2 = 0$, so this can be written as $x^2 + y^2 - z^2 = 0$ and then we get $-2x$ and we get $4z = 0$, so this is the required integral surface.

So in this lecture, we have looked at the initial value problem for the first order quasi-linear PDE. In the next lecture, we shall look at the existence and uniqueness of the solution of the quasi-linear PDE and we will discuss the Cauchy method to determine the solution of the first order quasi-linear PDE, uniqueness and existence problem we shall consider. Thank you very much for your attention.
