Lecture - 34
Existence and Uniqueness of Solutions

Hello friends. Welcome to my lecture on existence and uniqueness of solutions. First, we shall consider a quasi-linear partial differential equation of first order.

(Refer Slide Time: 00:38)

Let us consider first order quasi-linear PDE

$$P(x, y, z) \frac{\partial z}{\partial x} + Q(x, y, z) \frac{\partial z}{\partial y} = R(x, y, z) \quad (1)$$

Method for solving Cauchy problem for (1):

A Cauchy problem in mathematics asks for the solution of PDE that satisfies certain conditions that are given on a hypersurface of the domain. A Cauchy problem can be an IVP or BVP or it can be neither of them. It is named after Augustin-Louis Cauchy.

The Cauchy-Kowalevski theorem says that Cauchy problems have unique solutions under certain conditions.

The following theorem gives conditions under which a unique solution of the IVP for (1) can be obtained.

IIIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

Let us consider the equation as $P(x, y, z) \frac{\partial z}{\partial x} + Q(x, y, z) \frac{\partial z}{\partial y} = R(x, y, z)$. You can see that it is a quasi-linear PDE of first order. Now we shall be discussing the method for solving the Cauchy problem for this quasi-linear PDE. A Cauchy problem is what, a Cauchy problem in mathematics asks for the solution of partial differential equation that satisfy certain conditions that are given on a hypersurface of the domain.

A Cauchy problem can be an initial value problem or boundary value problem or it can be neither of them, it is named after Augustin-Louis Cauchy. The Cauchy-Kowalevski theorem says that the Cauchy problems have unique solutions under certain conditions. Let us discuss the theorem which gives the conditions under which a unique solution for the initial value problem for the first order quasi-linear PDE given by equation 1 can be obtained.

(Refer Slide Time: 01:47)

Theorem: Let $P(x,y,z)$, $Q(x,y,z)$ and $R(x,y,z)$ in (1) have continuous partial derivatives with respect to x , y and z . Let the initial curve be described as

$$x = x(s), y = y(s) \text{ and } z = z(x(s), y(s))$$

The initial curve C has a continuous tangent vector and

$$J(s) = \frac{dy}{ds}P(x(s), y(s), z(s)) - \frac{dx}{ds}Q(x(s), y(s), z(s)) \neq 0, \text{ on } C \quad (2)$$

Then, there exists a unique solution $z = z(x,y)$, defined in some neighbourhood of the curve C , satisfies (1) and the initial condition

$$z(x(s), y(s)) = z(s).$$

So let us discuss the theorem, it says that let $P(x, y, z)$; $Q(x, y, z)$ and $R(x, y, z)$ in the equation 1 have continuous partial derivatives with respect to x , y , and z and let us assume that the initial curve which we denote by C we described as $x=x(s)$, $y=y(s)$ and $z=z(x(s), y(s))$. The initial curve C we assume that has a continuous tangent vector and $J(s)$ which is given by $\frac{dy}{ds}P - \frac{dx}{ds}Q$ $x(s), y(s), z(s)$ is $\neq 0$ on the curve C .

Then, we can find a unique solution $z=z(x, y)$ defined in some neighborhood of the curve C which satisfies the equation 1 and the initial condition $z(x(s), y(s)) = z(s)$. So let us discuss the proof of this theorem.

(Refer Slide Time: 02:50)

Proof: From the existence and uniqueness theory of ODEs, the characteristic system

$$\left. \begin{aligned} \frac{dx}{dt} &= P(x(t), y(t), z(t)) \\ \frac{dy}{dt} &= Q(x(t), y(t), z(t)) \\ \frac{dz}{dt} &= R(x(t), y(t), z(t)) \end{aligned} \right\} \quad (3)$$

with initial conditions at $t=0$ given by

$$x = x(s), y = y(s) \text{ and } z = z(s)$$

From the existence and uniqueness theorem of the ordinary differential equations, we have already discussed that the existence and uniqueness theory of ordinary differential equations,

the characteristic system $dx/dt=P(x, y, z, t)$, $dy/dt=Q(x, y, z, t)$ and $dz/dt=R(x, y, z, t)$ with initial conditions at $t=0$.

(Refer Slide Time: 03:24)

possesses a unique solution of the form

$$x = x(s, t), y = y(s, t) \text{ and } z = z(s, t)$$

with continuous derivatives in s and t , and

$$x(s, 0) = x(s), y(s, 0) = y(s) \text{ and } z(s, 0) = z(s).$$

The Jacobian of transformation $x = x(s, t), y = y(s, t)$ at $t=0$ is

$$J(s) = J(s)|_{t=0} = \begin{vmatrix} \frac{\partial x}{\partial s} & \frac{\partial x}{\partial t} \\ \frac{\partial y}{\partial s} & \frac{\partial y}{\partial t} \end{vmatrix}_{t=0}$$

$$= \left(\frac{\partial y}{\partial t} \cdot P - \frac{\partial x}{\partial t} \cdot Q \right) \neq 0, \text{ in view of (3)}$$

At $t=0$, the initial conditions are $x=x(s)$, $y=y(s)$ and $z=z(s)$ possesses a unique solution of the form $x=x(s, t)$, $y=y(s, t)$ and $z=z(s, t)$ with continuous derivatives in s and t and at $t=0$ $x=x(s)$, y becomes $y(s)$ and $z=z(s)$. The Jacobian of the transformation $x=x(s, t)$, $y=y(s, t)$ at $t=0$ is given by $J(s)$ at $t=0$ which is $J(s)$ that is partial derivative of x with respect to s , partial derivative of x with respect to t then partial derivative of y with respect to s and then partial derivative of y with respect to t .

Now this is equal to partial derivative of y with respect to $t \cdot P$ - partial derivative of x with respect to $t \cdot Q$ and we have assumed that $J(s) \neq 0$ on C , so in view of our assumption this Jacobian does not vanish and we have also assumed that C has a continuous tangent vector.

(Refer Slide Time: 04:36)

By the continuity hypothesis, $J \neq 0$ in some neighbourhood of C . Applying implicit function theorem, s and t can be solved as functions of x and y near C . Hence

$$z(s, t) = z(s(x, y), t(x, y)) = z(x, y)$$

is a solution of (1) because

$$\begin{aligned} R = \frac{dz}{dt} &= \frac{dz}{dx} \frac{dx}{dt} + \frac{dz}{dy} \frac{dy}{dt} && \frac{\partial z}{\partial x} \frac{dx}{dt} + \frac{\partial z}{\partial y} \frac{dy}{dt} \\ &= P \frac{dz}{dx} + Q \frac{dz}{dy}, && = P \frac{\partial z}{\partial x} + Q \frac{\partial z}{\partial y} \end{aligned}$$

in view of (3).

So by the continuity hypothesis $J \neq 0$, this $J \neq 0$ in some neighborhood of the curve C . Now let us apply the implicit function theorem and when we apply the implicit function theorem it follows that s and t can be solved as functions of x and y near C okay. So z s , t is now z of s , x , y and t x , y , s and t are now functions of x and y because that follows from the implicit function theorem.

So z is also a function of x and y , z s , t becomes a function of x and y , so this is a solution of 1. Now this z s , t z x , y is the solution of 1 because $R = dz/dt$ from the characteristic theorem $R = dz/dt$ and dz/dt now can be written as $dz/dx * dx/dt$ because z is a function of x and y , so $dz/dx * dx/dt + dz/dy * dy/dt$ and from the characteristic system we know that $dx/dt = P$ and $dy/dt = Q$ so $P * dz/dx + Q * dz/dy$.

There should not be actually the partial derivatives, we should be writing like this. This should be replaced by this and then this should be $= dx/dt$ is P , so P partial derivative of z with respect to $x + Q$ times partial derivative of z with respect to y okay. So when z s , t is expressed as a function of x and y okay we find that it is a solution of 1 because $R =$ when we find dz/dt it turns out that it is $= P$ partial derivative of z with respect to $x + Q$ partial derivative of z with respect to y which is $= R$.

So $R =$ this and therefore z is a solution of $z = z$ x , y is a solution of the given quasi-linear partial differential equation of first order.

(Refer Slide Time: 07:10)

The solution is unique because by the uniqueness theorem for the IVP for (3), any two integral surfaces that contain the same initial curve coincide along all the characteristic curves passing through the initial curve C.

Example: Let us consider the IVP

$$zp + q = 0,$$

$$z(x, 0) = f(x)$$

where $f(x)$ is a smooth function.

Handwritten notes in red ink:

- $P(x, y, z) = z$
- $Q(x, y, z) = 1$
- $R(x, y, z) = 0$
- We parameterize the initial curve C by taking $x=s, y=0, z=f(s)$
- by taking $x=s, y=0, z=f(s)$
- The characteristic equations are $\frac{dx}{dt} = z, \frac{dy}{dt} = 1, \frac{dz}{dt} = 0$
- $\frac{dx}{dt} = z \Rightarrow \frac{d^2x}{dt^2} = \frac{dz}{dt} = 0$
- $\frac{d^2x}{dt^2} = 0 \Rightarrow \frac{dx}{dt} = c_1(s)$
- $\frac{dx}{dt} = c_1(s) \Rightarrow x(s, t) = c_1(s)t + s$
- $\frac{dy}{dt} = 1 \Rightarrow y = t$
- $\frac{dz}{dt} = 0 \Rightarrow z = c_2(s)$
- $z = c_2(s)$
- At $t=0, we are given $z=s$$
- $\Rightarrow \Delta = z - f(s) = z - z = 0$

Now let us look at the unicity of this solution. The solution is unique because by the uniqueness theorem for the initial value problem for the characteristic system 3, for this system the uniqueness follows because any 2 integral surfaces that contain the same initial curve coincide along all the characteristic curves which pass through the initial curve C, so this is how we prove the existence and uniqueness of the solution of quasi-linear PDE.

So we have discussed the method for solving the Cauchy problem for this quasi-linear PDE. Now let us apply this result, so let us consider the initial value problem $zp+q=0$ and where $z(x, 0)$ is given=so initial condition is given $z(x, 0)=f(x)$ where $f(x)$ is a smooth function. Now what we do, so here when we compare this with the given form 1 then what do we notice, let us write the values of P, Q and R.

So $P(x, y, z)=z$; $Q(x, y, z)=1$ and $R(x, y, z)=0$, what we do is to solve this initial value problem let us first parameterize the curve C okay. So let us first parameterize the initial curve, so we parameterize the initial curve C by taking $x=s$ so let us take $x=s, y=0$ then $z=f(s)$ okay. Now the characteristic equations are $dx/dt=P$ so we get $z, dy/dt=Q$ so we get $1, dz/dt=R$ so we get 0 okay.

Now what do we get $dx/dt=z$, so this gives you $d^2x/dt^2 = dz/dt$ and $dz/dt=0$, so what do we get, $d^2x/dt^2=0$, x is a function of s and t . So when we integrate $d^2x/dt^2=0$ twice with respect to t what do we get, if you integrate it once we get $dx/dt=c_1(s)$ okay, we are integrating with respect to t keeping s as a fixed quantity.

So $dx/dt=c_1 s$ and when we integrate it once more we get $x s, t=c_1 s^*t+c_2 s$ okay. Now we are given that $t=0$, at $t=0$ $x=s$ okay, so what do we do, at $t=0$ we are given $x=s$ and when we put $t=0$ in this $x s, t$ becomes s , so what do we get $c_2 s=s$ okay, so we get $x s, t=c_1 s+s$ okay and when we differentiate it $dx/dt=$ what we get $c_1 s^*t+c_2 s, c_2 s=s$ because at $t=0$ $x s, t=s$ and then $dx/dt=c_1 s$ from here so what do we get, at $dx/dt=z$ so $z=c_1 s$ okay.

We are given $dx/dt=z$, so this we get $x s, t=c_1 s=z$ so z^*t+s . This is $x s, t$ and $dy/dt=1$ gives you $y=t+some\ constant\ c_3 s$. Now at $t=0, y=0$, so what do we get, $0=0+c_3 s$ so $c_3 s=0$ gives you $y=t$ okay, so we have $x s, t=zt+s$ $y=t$ and $dz/dt=0$ gives you $z=c_4 s$. Now at $t=0, z=f s$, so what do we get $f s=c_4 s$. So we get $z=f s$ okay. So we have solved this system of characteristic system.

We have got $x=zt+s, y=t, z=f s$ okay so what do we get now then. We can write $x s, t$ okay in terms of s and t we want to write. So z we will put as $f s$ so $f s^*t+s, y=t$ and $z=f s$ okay. Now using $y=t$ we can write $x s, t=f s^*y+s$, so we need to solve this system for the values of s and t in terms of x and y okay. We have to write s as x, y $s x, y$ and t as $t x, y$. So what do we get we can write $s=x-f s^*y$ or $x-zy$.

So we get $s=x-zy$ and $z=f s$ so what do we get $z=f s$ gives you f of $s=x-zy$, so what do we get is the solution of the given initial value problem is then obtained in an implicit form $z=f$ of $x-zy$.

(Refer Slide Time: 16:00)

Then the solution is given by

$$z = f(s) = f(x - yz).$$

IIT Kharagpur NPTEL ONLINE CERTIFICATION COURSE 8

So the solution is $z = f(s)$ and s is $x - yz$, so the solution is obtained in the form of an implicit equation.

(Refer Slide Time: 16:11)

Example: Let us consider the quasi-linear PDE
 $zp + yq = x$
 where the initial condition is given by
 $z(x, 1) = 2x.$

The characteristic system is
 $\frac{dx}{z} = \frac{dy}{y} = \frac{dz}{x}$
 The parametric form of the curve C is
 $x = b, y = 1, z = 2b$

Solving the characteristic system we get
 $\frac{dx}{z} = \frac{dy}{y} \Rightarrow \frac{dx}{2t} = \frac{dy}{1} \Rightarrow x = \frac{b}{2}(3t-1)$
 $\frac{dy}{y} = \frac{dz}{x} \Rightarrow \frac{dy}{1} = \frac{dz}{2t} \Rightarrow y = c_1 e^{t/2} + c_2 e^{-t/2}$
 At $t=0, y=1$ so
 $1 = c_1 + c_2$ and hence
 $c_1 = \frac{1+z}{2}, c_2 = \frac{1-z}{2}$

At $t=0, z=2b$ so
 $2b = c_1(1) + c_2(1) \Rightarrow c_1 = \frac{3b}{2}, c_2 = -\frac{b}{2}$

Thus, $x(b, t) = \frac{3b}{2} e^{t/2} - \frac{b}{2} e^{-t/2} = \frac{b}{2} (3e^{t/2} - e^{-t/2})$

Now let us consider another problem suppose we have the quasi-linear PDE, $zp + yq = x$ where the initial condition is given by $z(x, 1) = 2x$. So let us write the characteristic system here. The characteristic system is dx/P okay let us write like this $dx/dt = P$ that is z , $dy/dt = Q$ which is y and then $dz/dt = x$, so we get the characteristic equations $dx/dt = P$ x, y, z P x, y, z is z ; $dy/dt = Q$ x, y, z which is y , dz/dt which is x .

And let us parameterize the parametric form of the curve C , so what we do, let us put $x = s$, $y = 1$ and $z = 2s$ okay. So if we do this what we will get then let us solve this characteristic system. Solving the characteristic system, we get $dx/dt = z$, see $dx/dt = z$ so we get $d^2x/dt^2 = dz/dt$ and $dz/dt = x$, so we get $d^2x/dt^2 = x$ and this is nothing but $d^2x - 1x = 0$ where d denotes d/dx .

So solving this second order linear differential equation in x what we get is the general solution x is equal to because the auxiliary equation is $m^2 - 1 = 0$, so this gives 2 distinct roots $m = +1$ and corresponding to 2 distinct roots of the auxiliary equation we have the solutions e to the power t and e to power $-t$ of this equation so $c_1 s * e$ to the power $t + c_2 s * e$ to the power $-t$ we can write for x , this x is $x(s, t)$.

Now what we have at $t = 0$ we are given $x = s$, so we have $s = c_1 s + c_2 s$. Now we need to find one more condition in order to determine c_1 and c_2 . So we use the condition that $dx/dt = z$, so

$dx/dt=z$ and dx/dt here is what $c_1 s^*$ e to the power $t+c_2 s^*$ e to the power $-t$. Now dx/dt is z , $z=c_1 s$ e to the power $t+c_2 s$ e to the power $-t$, put $t=0$ at $t=0$ $z=2s$, so $2s=c_1 s$, when we differentiate we should have got a negative sign here, so this is negative okay.

So $-c_2 s$ okay, now let us solve this equation and this equation for the values of c_1 and c_2 . So when we add them we get $2c_1 s=3s$ so $c_1 s=3s/2$ and $c_1 s=3s/2$ means $c_2 s=-s/2$ okay. Thus, we have solved this equation $d^2 x/dt^2=s$ and we got $x s, t=3s/2$ e to the power $t-s/2$ e to the power $-t$ okay. Now we have the second equation $dy/dt=y$, so $dy/dt=y$ gives you $dy/y=dt$ which gives $\ln y=t+\ln$, let us say $c_3 s$. So what we get $y=c_3 s$ times e to the power t .

At $t=0$ we are given $y=1$, so $1=c_3 s$ and hence we get $y=e$ to the power t . Now let us solve for z . We have $dz/dt=x$. So let us differentiate once more we get $d^2 z/dt^2=dx/dt$ which is $=z$. So we get again $d^2 z-1 z=0$ which gives you $z s, t=\text{some constant } c_4 s^*$ e to power $t+c_5 s$ e to the power $-t$. We put $t=0$, at $t=0$ $z=2s$ so $2s=c_4 s+c_5 s$. So we have got one condition involving c_4 and c_5 .

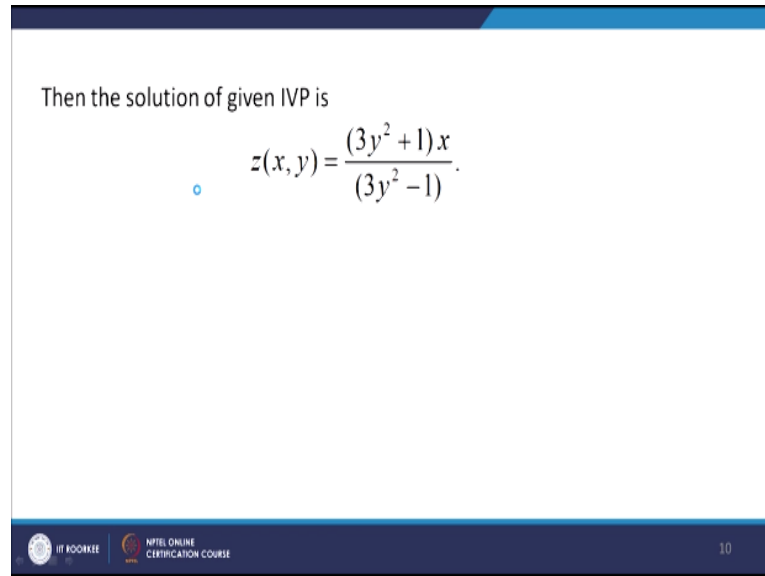

We need one more condition in c_4 and c_5 to determine their values, so let us find dz/dt , $dz/dt=c_4 s$ e to the power $t-c_5 s$ e to the power $-t$ and $dz/dt=x$. So we get at $t=0$, x is given to be $=s$, so $s=c_4 s-c_5 s$ okay. Now let us take this equation and this equation and then determine the values of c_4 and c_5 . So when we add this equation with this we get $c_4 s=3s$, so $c_4 s$ then $=3s/2$ and $c_5 s$ will then be $=s/2$.

And so $z s, t$ will be $=3s/2$ e to the power $t+s/2$ e to the power $-t$ okay, so we have got the values of $x s, t; y s, t; z s, t$ as functions of s and t . Let us now solve them to determine s as a function of x and y and t also as a function of x and y . So from this equation let us see, this is equal to we can write $s/2$ times 3 e to the power $t-e$ to the power $-t$ okay. Now we use this equation $y=e$ to power t so $s=s/2$ $3y-1/y$ okay.

Ad this gives you what we get $x=3s/2$ and we get $3y$ square $-1/y$ okay. So $s=$ we can find s in terms of x and y here, $2xy/3y$ square -1 . Now what we do here $s=s/2$ $3e$ to the power $t+e$ to the power $-t$ so $3y+1/y$ okay and this gives you $s/2$ $3y$ square $+1/y$ okay. Now we can use the value of s as $2xy/3y$ square -1 here and get the value of z in terms of x and y . So $z=s/2$, $s/2$ is $xy/3y$ square $-1*3y$ square $+1/y$.

So this I can cancel and I get x times $3y^2 + 1/3y^2 - 1$. So we have got $z = x$ times $3y^2 + 1/3y^2 - 1$ which is in explicit solution of the given quasi-linear PDE $z = 3y^2 + 1/x/3y^2 - 1$.

(Refer Slide Time: 27:32)

Then the solution of given IVP is

$$z(x, y) = \frac{(3y^2 + 1)x}{(3y^2 - 1)}$$

The slide features a blue header and footer. The footer contains the IIT Kharagpur logo, the text 'IIT KHARAGPUR', 'NPTEL ONLINE CERTIFICATION COURSE', and the page number '10'.

So this is how we solve the quasi-linear PDE $z_p + yq = x$ where the initial condition is given by $z = x, 1 = 2x$. So with this I would like to end my lecture. Thank you very much for your attention.
