

**An Introduction to Smooth Manifolds**  
**Professor. Harish Seshadri**  
**Department of Mathematics,**  
**Indian Institute of Science, Bengaluru**  
**Lecture 31**  
**Lie Groups 1**

So hello and welcome to the 31st lecture in the series. And I was giving some examples of vector fields last time.

(Refer Slide Time: 0:38)

$U_1$   $\left\langle \frac{\partial}{\partial x}, \frac{\partial}{\partial y} \right\rangle$  independent.

3) on  $S^1 \subseteq \mathbb{R}^2$ , let  
 $X_{(x,y)} = y \frac{\partial}{\partial x} - x \frac{\partial}{\partial y}$   
 i)  $X_{(x,y)} \in T_{(x,y)} S^1$

If we regard  $T_p S^1 \subseteq T_p \mathbb{R}^2 = \mathbb{R}^2$ ,  
 Then  $T_p S^1 = \{ v \in \mathbb{R}^2 : \langle v, p \rangle = 0 \}$   
 Note that  $X_{(x,y)} = (y, -x)$   
 $p = (x, y)$   
 Hence  $X_{(x,y)} \in T_{(x,y)} S^1$

$\mathbb{R}^k$

Note that  
 since that  $\frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_n}$  belong to  
 $T_p S$ .

In fact on  $S^{2n+1} \subseteq \mathbb{R}^{2n+2}$   $n \geq 0$   
 $p = (x_1, x_2, \dots, x_{2n+1}, x_{2n+2}) \in S^{2n+1}$

3) on  $S^1$

$$X_{(x,y)} = y \frac{\partial}{\partial x} - x \frac{\partial}{\partial y}$$

i)  $X_{(x,y)} \in T_{(x,y)} S^1$

If we regard  $T_p S^1 \subseteq T_p \mathbb{R}^2 = \mathbb{R}^2$

Then  $T_p S^1 = \{ v \in \mathbb{R}^2 : \langle v, p \rangle = 0 \}$

Note that  $X_{(x,y)} = (y, -x)$   
 $p = (x, y)$

Hence  $X_{(x,y)} \in T_{(x,y)} S^1$

ii) Smoothness of  $X$  as a vector field on  $S^1$

In fact on  $S^{2n+1} \subseteq \mathbb{R}^{2n+2}$   $n \geq 0$

$$p = (x_1, x_2, \dots, x_{2n+1}, x_{2n+2}) \in S^{2n+1}$$

$$X_p = (-x_2, x_1, 0, \dots, 0) \in T_p S^{2n+1}$$

$$X_p = (-x_2, x_1, -x_4, x_3, \dots, -x_{2n+2}, x_{2n+1}) \in T_p S^{2n+1}$$

So, in particular I had this I gave an example of a vector field on  $S^1$ . The point  $X$   $Y$ , I am looking at  $X$ ,  $x$   $y$ . Now notice that, yeah in fact this it can be, this example can be generalized to all odd dimensional spheres. In fact on  $S^{2n+1}$  contained in  $\mathbb{R}^{2n+2}$  for any  $n$  bigger than or equal to 0.

I can write down a similar vector field. So, let us start with a point  $x_1$   $P$  equals  $x_1$   $x_2$   $x_{2n+1}$   $x_{2n+2}$ . So, let us start with this point in the sphere,  $2n+1$  dimensional sphere. Again, the tangent space to the sphere in any dimension we know is given by the regular value theorem. The tangent space is still given by the right hand side. It looks at the point  $P$  it consists of all vectors  $v$  such that  $v$  in a product with  $P$  is 0 and the subspace of the ambient Euclidean space.

So in this case too, that is the case, so I just to come up with a vector field, I just use  $X_p$  well I just take minus  $x_2 x_1$ . And I just put 0's as well. This will give me a smooth vector field on the  $2n$  plus 1 dimension sphere and in fact, I can play around with this and come up the other ones as well. Yes, that is or another example would be  $X_p$ , I do this on each pair of variables minus  $x_2 x_1$  minus  $x_3$  rather  $x_4 x_3$  and so on minus  $x_{2n+2} x_{2n+1}$ .

All I have to do is ensure that  $X_p$  is perpendicular to  $P$  which is this,  $P$  is here, so the way I have written it is that is perpendicular to this. So, each of this, this or this gives rise to a smooth vector field on two dimensional sphere. So, this is in  $TP S^{2n+1}$  and so is this and this smoothness again. These are all even though I have defined it only for  $P$  raised to  $2n+1$  if I use the same formula this is a vector field on defined on the whole of  $R^n$ , whole of  $R^2$  in plus 2.

So, but it is just so we again use this small proposition here that if I have a vector field on the whole manifold, such which is tangent to the sub manifold at each point, then the restricted vector thing is also sooth. So these are all smooth vector fields. The last one, this is especially interesting because it gives rise to a vector field on the sphere, which is not zero at any point. It cannot happen that this, you get the 0 vector because if this is 0, then the coordinate vector would also be 0.

$P$  would also be 0 which is not the case since  $P$  belongs to  $S^{2n+1}$ . So the existence of a vector field which is not 0 at any point is related to some questions in topology, but we are not going to go into that. Instead, let us talk about this is the right place to talk about lie groups. So, this was example number three. Now, I am moving on to example number 4.

(Refer Slide Time: 6:12)

$X_p = (-x_2, x_1, -x_4, x_3, \dots, -x_{2n+2}, x_{2n+1}) \in T_p S^{2n+1}$

4) Lie groups and Lie algebras:

Let  $G$  be a manifold with a group structure which is compatible with the smooth structure in the following sense:

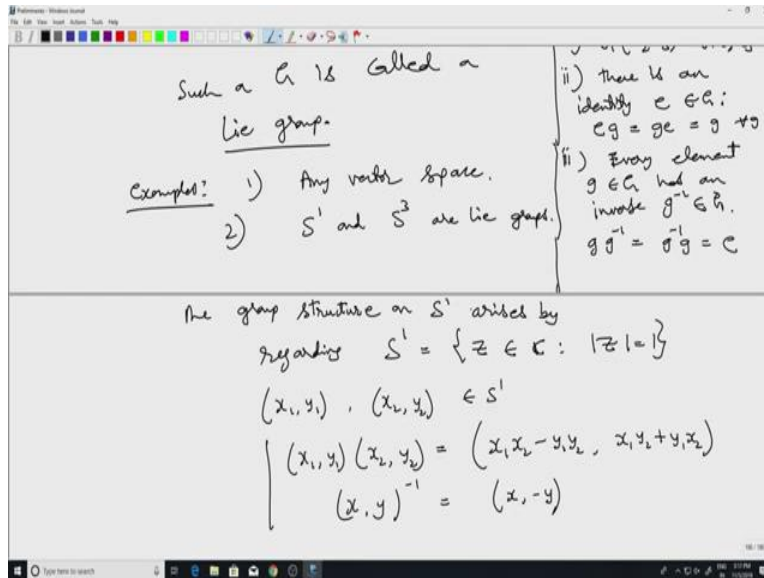

The map  $G \times G \rightarrow G$   
 $(x, y) \rightarrow xy$   
and

in the following sense:

The maps  $G \times G \rightarrow G$   
 $(x, y) \rightarrow xy$   
and  
 $G \rightarrow G$   
 $x \rightarrow x^{-1}$   
are smooth.

A group  $G$  is a set with a binary operation (group multiplication)  
 $G \times G \rightarrow G$   
such that

- i)  $g_1(g_2g_3) = (g_1g_2)g_3$
- ii) there is an identity  $e \in G$ :  
 $eg = ge = g \forall g$
- iii) Every element  $g \in G$  has an

Lie groups and Lie algebras. So let  $G$  be a manifold with a group structure. I will quickly recall what I mean a group structure is but let us assume for the moment, let us proceed with a group structure which is compatible with the smooth structure in the following sense. I just demand that group multiplication which is a map from  $G \times G$  to  $G$  and  $G$  going to  $G$ ,  $X$  going to  $X$  inverse. I demand that these two maps so the maps, these two maps are smooth.

So well, so in order for this to make sense, we need a notion of a group, so groups is a set, set with a binary operation. Also core group multiplication and what a binary operation just means that if you start with two the same thing that I have written here  $G \times G$  to  $G$ . So binary operation is just a map from  $G \times G$  to  $G$ , but satisfying such that one  $G$  operation is associated. So in other words,  $G_1 G_2 G_3$  is  $G_1 G_2 G_3$ .

Secondly, there is an identity each and the definition of an identity is that  $e g$  equals  $g e$  equals  $G$  for all  $G$ . And every element  $g$  in  $G$ , as an inverse and this definition of inverse is that  $g g$  inverse equals to  $g$  inverse  $g$  equal to identity so that is a group. So now the thing is that but here normally when one first sees this notion of a group, this  $g$  will be a typically a finite set, say the group of permutations, etc.

Now here it is definitely not going to be a finite set. Third dimension of  $M$  and dimension is greater than 1, dimension is at least one, so let  $g$ , here we are having a manifold and which has a

group structure as well which is compatible with the smooth structure. It is not that the group structure and the manifold structure should be completely independent. They should be related in the following sense that the group multiplication and inversion operations are smooth maps.

Here  $G \times G$  is regarded as a product manifold but one of the good things is that one has lots of natural examples of this, so, such as  $\mathbb{R}^n$  I called a Lie group. So one can think of it as a manifold, which is a group or a group which is also a manifold, so examples any vector space is trivially a Lie group. Now, the group operation here, the binary operation here is just addition of vectors. Even though here I said the binary operation is called group multiplication.

When we are in the context of vector space, multiplication means actually addition here, addition of vectors. So, any vector space with vector addition is a group and we know that vector spaces are also manifolds and we know that the addition operation is smooth. To say the addition operation and the inversion operation is just  $x$  going to  $-x$  in this case and those are smooth simply because ultimately the manifold structure comes from identifying  $n$  dimensional vector space with  $\mathbb{R}^n$ .

And when we do that, this addition in the vector space just corresponds to a usual addition of vectors in  $\mathbb{R}^n$  and so it is certainly smooth. Now, more interesting examples come from looking at matrix groups, which I will talk about shortly, but before that, it turns out that there are even spheres, some of them are grouped so let  $S^1$  for example is a Lie group and in fact it turns out that  $S^1$  and  $S^3$  are Lie groups.

Let me just take the case of  $S^1$ . Now, the group operation on  $S^1$  is comes from regarding  $S^1$  as the set of complex numbers with modulus one. And if you think of it  $S^1$  like that way, then of course we can multiply two complex numbers. And if both have modulus 1, then so does the product. The groups structure on  $S^1$  arise by regarding  $S^1$  as set of all  $z \in \mathbb{C}$  with  $|z| = 1$ .

So if you think of it like that, then  $z_1 z_2$ , we just do usual complex multiplication, of course this is how one gets a structure, but ultimately one does not have to mention complex numbers at all. So, one just uses this complex numbers as a motivation and then define. So, if I just start with  $x_1, y_1, x_2, y_2$  in  $S^1$ , then I will define the product  $x_1 y_1$  times  $x_2 y_2$  to be well I just do complex

multiplication of  $x_1 + iy_1$   $x_2 + iy_2$  that will give the  $x_1 x_2 - y_1 y_2$  and then  $x_1 y_2 + y_1 x_2$ , not  $y_1 x_2$ .

This if I write it like this, it is not entirely clear how we came up with the right hand side but since I have already said that structure, so here I need structure on this one arises right. So I have already said that one can think of  $S^1$  as complex numbers with unit modulus and then one can get distracted. So, this is how, so this is the group operation and we know that  $S^1$  is indeed a group. The identity element is literally the complex number 1, which would correspond to the point 1 common 0 in  $\mathbb{R}^2$ .

And we know that the inverse of  $a$ , an element with modulus 1 is also another element with modulus 1. So, this is the operation and in fact the inverse I can even write down the inverse. So inverse of  $x + iy$  is just, it says of the complex conjugate of this. So it is  $x - iy$ . So and so this since we have explicit formulas for group multiplication and the inversion operations, it is immediately clear that again, we are using the fact that these operations are actually well defined maps on all of  $\mathbb{R}^2$ , so then we restricted to  $S^1$ , we will continue to get smooth maps.

So therefore the group compatibility condition which I talked about here this stuff is satisfied for  $S^1$  with this operation, so  $S^1$  becomes a lie group. The group structure on  $S^3$  is well again, one can think of  $S^3$  as a subset of  $\mathbb{R}^4$  which is  $\mathbb{C} \times \mathbb{C}$ . However, it is the  $\mathbb{C} \times \mathbb{C}$  with all those elements with norm equal to 1, however the group structure on  $S^3$  is not immediately, it is not clear.

In fact the  $S^1$  the group operation on  $S^1$  has since it is coming from  $\mathbb{C}$  complex multiplication, it is just an commutative a billion group. It does not matter whether I do  $x_1 y_1$  whether I put this one first or  $x_2 y_2$  first I get the same answer. But the group operation  $S^3$  is actually it is a non a billion group operation and it is not it immediately clear how to how one sees that lie group, but it is not that difficult either.

(Refer Slide Time: 21:00)

$(x, y) = (x, -y)$

3)  $GL(n, \mathbb{R}) \xrightarrow{\varphi_1} GL(n, \mathbb{R})$   
 $GL(n, \mathbb{R}) \times GL(n, \mathbb{R}) \xrightarrow{\varphi_1} GL(n, \mathbb{R})$   
 $(A, B) \xrightarrow{\varphi_1} AB$   
 $GL(n, \mathbb{R}) \xrightarrow{\varphi_2} GL(n, \mathbb{R})$   
 $A \xrightarrow{\varphi_2} A^{-1}$

The entries of  $A^{-1}$  are rational functions in the entries of  $A$  with denominator =  $\det A$

Hence,  $O(n, \mathbb{R})$  and  $SL(n, \mathbb{R})$  are Lie groups as well.

Note that

$O(n, \mathbb{R}) \times O(n, \mathbb{R}) \xrightarrow{\varphi_1} O(n, \mathbb{R})$   
 $SL(n, \mathbb{R}) \times SL(n, \mathbb{R}) \xrightarrow{\varphi_1} SL(n, \mathbb{R})$

$O(n, \mathbb{R}) \xrightarrow{\varphi_2} O(n, \mathbb{R})$   
 $SL(n, \mathbb{R}) \xrightarrow{\varphi_2} SL(n, \mathbb{R})$

The entries of  $A^{-1}$  are rational functions in the entries of  $A$  with denominator =  $\det A$

Hence,  $O(n, \mathbb{R})$  and  $SL(n, \mathbb{R})$  are Lie groups as well.

Note that

$O(n, \mathbb{R}) \times O(n, \mathbb{R}) \xrightarrow{\varphi_1} O(n, \mathbb{R})$   
 $SL(n, \mathbb{R}) \times SL(n, \mathbb{R}) \xrightarrow{\varphi_1} SL(n, \mathbb{R})$

$O(n, \mathbb{R}) \xrightarrow{\varphi_2} O(n, \mathbb{R})$   
 $SL(n, \mathbb{R}) \xrightarrow{\varphi_2} SL(n, \mathbb{R})$

By our earlier remarks about smooth maps restricted to submanifolds, we see that the restricted maps are smooth.

But however, I will not go into that instead I will talk a bit about matrix groups, which are the most important classes of lie groups. So first, let us start with  $GL_n \mathbb{R}$ . Now here it is the operation is just matrix multiplication group operation is matrix multiplication. And if so, one has to check that  $GL_n \mathbb{R} \times GL_n \mathbb{R} \rightarrow GL_n \mathbb{R}, (A, B) \mapsto AB$  going to a times b. Whether this map is smooth or not, well we do know that first of all  $GL_n \mathbb{R}$  we have seen is just an open subset of  $M_n \mathbb{R}$  of the set of all  $M$  cross  $N$  matrices, which is  $\mathbb{R}^{n^2}$ .

So, when talking about smoothness, we can just use the fact that there is an open subset. And so the issues regarding smoothness are just, we can think of this as maps of corresponding the Euclidean space  $\mathbb{R}^n$  square cross  $\mathbb{R}^n$  square to  $\mathbb{R}^n$  square and matrix multiplication is just corresponds, it will give rise to a polynomial map. These variables input variables, so therefore this is smooth.

And similarly, inversion  $GL_n(\mathbb{R})$  with  $GL_n(\mathbb{R})$  the map is a going to a inverse. Here it is still smooth but it is certainly not going to be a polynomial operation. The entries of a inverse or not polynomials and the entries of  $A$  but the next best thing, their rational functions. So entries of a inverse or polynomials in the entries of  $A$ , oh not polynomials rational functions, the ratio of two polynomials.

Well, rational functions can cause problems if the denominators becomes 0, but here the denominator we know is denominator equals to just the determinant of  $A$ . And since  $A$  belongs to this opens set  $GL_n(\mathbb{R})$ , it is not going to be 0 anywhere on this set. So it is a rational entries of  $A$  inverse rational functions with non-zero denominator. Therefore, it will also be they will be smooth. So both of these are smooth therefore  $GL_n(\mathbb{R})$  is a lie group.

Once we have this, we can immediately see that. Hence, we do not have to repeat the calculation here. Hence  $O_n(\mathbb{R})$  the other two matrix group consider it  $\mathbb{R}$ , these two are lie groups as well. Well, why? Yeah. So I read this word hence, so this is supposed to follow from whatever this discussion of  $GL_n(\mathbb{R})$  and that is again to do with the fact that these are sub manifold of  $GL_n(\mathbb{R})$ . Note that, these operation matrix multiplication, so let us call this one as  $\phi_1$  and this is  $\phi_2$ .

Matrix multiplication and inversion  $\phi_1$ , when I do  $O_n(\mathbb{R})$  times  $O_n(\mathbb{R})$  or not, we know that the product of two orthogonal matrices is after all this is a subgroup, so matrix multiplication preserves. So the same  $\phi_1$  that I had here when I restricted to  $O_n(\mathbb{R})$  cross  $O_n(\mathbb{R})$ , it will go back to  $O_n(\mathbb{R})$  and similar thing for  $SL_n(\mathbb{R})$  as well. And I take and I restrict the product operation. This is the very definition of a subgroup.

So I had  $\phi_1$ , similarly  $\phi_2$  will take  $O_n(\mathbb{R})$  and  $SL_n(\mathbb{R})$  to  $SL_n(\mathbb{R})$ , so since we have already established that  $\phi_1$  and  $\phi_2$  are smooth on the big manifold  $GL_n(\mathbb{R})$ . We can use our earlier remarks about smoothness of maps, then districted to sub manifolds to conclude that this  $\phi_1$

and  $\phi^2$  when regarded as maps from  $\text{OnR} \times \text{OnR}$  to  $\text{OnR}$  and  $\text{OnR}$  to  $\text{OnR}$ , similar for  $\text{SLnR}$ , they are also smooth.

So we conclude that by our earlier remarks about smooth maps, restricted to sub manifolds, both in the domain and image, we see that the restricted maps are smooth. Therefore, we get that these are lie groups as well. Now, the reason for mentioning for bringing up this notion of a lie group in the context of vector fields after all we talking about vector fields is not clear from what I have said so far.

So, in my next lecture, I will talk briefly about that. That vector fields on lie groups see the role that they have to play. So okay, so we will end the lecture today at this stage. Thank you.
