Hello everyone. So, in last class we have solved the velocity distribution and the volume flow rate for Hagen Poiseuille flow. You have learnt how to derive the ordinary differential equation from the Navier Stoke equations using the assumptions. So, today we will also solve two problems Thin Film Flow and Annular Flow in cylindrical coordinate.

(Refer Slide Time: 01:00)

### Film Flow Down a Vertical Cylinder

Laminar, steady, incompressible fully-developed axisymmetric flow with constant fluid properties.  
 Surface tension is zero, so film is of uniform thickness.  
 The air is stationary.

$$0 = -\frac{\partial p}{\partial z} + \rho g_z + \mu \frac{1}{r} \frac{d}{dr} \left( r \frac{dv_z}{dr} \right)$$

$$v_z = v_z(r)$$

$$\frac{\partial p}{\partial z} = 0 \quad g_z = g$$

$$\frac{d}{dr} \left( r \frac{dv_z}{dr} \right) = -\frac{r}{\mu} \rho g$$

$$r \frac{dv_z}{dr} = -\frac{r^2}{2\mu} \rho g + c_1$$

$$\frac{dv_z}{dr} = -\frac{r}{2\mu} \rho g + \frac{c_1}{r}$$

$$v_z(r) = -\frac{\rho g}{4\mu} r^2 + c_1 \ln r + c_2$$

Boundary Conditions:

@  $r = R$ ,  $v_z = 0$        $c_2 = \frac{1}{4\mu} \rho g R^2 - c_1 \ln R$

@  $r = R + \delta$ ,  $\frac{dv_z}{dr} = 0$      $\Rightarrow c_1 = \rho g \frac{(R + \delta)^2}{2\mu}$

$\tau_{rz} = \mu \frac{dv_z}{dr}$   
 @  $r = R + \delta$ ,  $\tau_{rz} = 0$

So, first let us consider film flow down a vertical cylinder. So, you can see a Newtonian liquid is flowing down in the outer surface of a infinitely long cylinder of radius  $r$ , this is the cylinder with radius  $r$ . And outside you can see it is a thin liquid film of thickness  $\delta$ . And outside of this film we have air which is stationary.

So, the coordinate is taken  $r$  in this direction and  $z$  in the downward direction. And, in this case we are assuming laminar steady incompressible fully developed axisymmetric flow with constant fluid properties. So, as it is axisymmetric flow so, you know that the circumferential direction velocity is 0 and the gradient in that direction of any parameter is 0.

We are assuming surface tension is 0 so the film has the uniform thickness  $\delta$ . And the air is stationary such that the shear stress is 0 at the interface. So, you can see this is the cylinder actually and outside you have thin film of thickness  $\delta$ . So, you can see that in this direction gravity will be there and let us say this is  $g$  acting in the positive  $z$  direction. So, we will start with the ordinary differential equation which we derived in the last class.

So, you know that we have derived in last class  $0 = -\frac{dp}{dz} + \rho g - \mu \frac{1}{r} \frac{d}{dr} \left( r \frac{dv_z}{dr} \right)$  and you have plus  $\mu \frac{1}{r} \frac{d}{dr} \left( r \frac{dv_z}{dr} \right)$ . So,  $v_z$  is the axial velocity and you know that  $v_z$  is function of  $r$  only ok. So, in this case; obviously, you can see that it is a gravity driven flow, because  $\frac{dp}{dz}$  will be 0.

So, in this case  $\frac{dp}{dz}$  is 0 and due to gravity actually this liquid will go down along the  $z$  direction. And let us say in this direction we have the gravity  $g$  so; obviously,  $g$  is equal to  $g$ . So, if you rearrange it you will get  $\frac{d}{dr} \left( r \frac{dv_z}{dr} \right) = \frac{r}{\mu} g$ .

So, this equation now you can integrate twice and you will get the velocity distribution, and the integration constant you can find invoking the two boundary conditions. So, what are the boundary conditions? Obviously, at the cylinder surface at  $r = r$  velocity is 0  $v_z$  is equal to 0. And at the interface at  $r = r + \delta$  the shear stress is 0.

So, if you integrate twice you will get  $r \frac{dv_z}{dr}$  is equal to  $-\frac{r^2}{2} \mu \rho g + c_1$ . And, if you integrate then you will get  $v_z$  which is function of  $r$  only as  $\rho g \frac{r^2}{4\mu} + c_1 \ln r + c_2$ . And what are the boundary conditions?

Boundary conditions at  $r = R$   $v_z = 0$  and at  $r = R + \delta$  which is your interface  $\frac{dv_z}{dr} = 0$ , why? Because  $\tau_{rz} = \mu \frac{dv_z}{dr}$  right. And  $\tau_{rz} = 0$  at  $r = R + \delta$   $\tau_{rz} = 0$ . So, hence  $\frac{dv_z}{dr} = 0$ .

So, if you put it so, you will get  $c_1 = \frac{\rho g R^2}{2\mu}$ . And, if you invoke  $r = R$   $v_z = 0$  from here you will get  $c_2 = \frac{1}{4\mu} \rho g R^2 - c_1 \ln R$ .

(Refer Slide Time: 06:47)

### Film Flow Down a Vertical Cylinder

velocity distribution,

$$v_z(r) = \frac{\rho g}{4\mu} \left[ R^2 - r^2 + 2(R+\delta)^2 \ln \frac{r}{R} \right]$$

Shear stress,

$$\tau_{rz} = \mu \frac{dv_z}{dr} = \frac{\rho g}{2} \left[ \frac{(R+\delta)^2}{r} - r \right]$$

@  $r = R + \delta$ ,  $\tau_{rz} = 0$   
 @  $r = R$ ,  $\tau_{rz}|_{r=R} = \frac{\rho g}{2} \left[ \frac{R^2 + 2\delta R + \delta^2}{R} - R \right]$   
 $= \frac{\rho g}{2} \frac{\delta}{R} (2R + \delta)$

Now you put this values in this velocity distribution, and you will get final expression for velocity distribution as  $v_z$ , which is function of  $r$  is equal to  $\frac{\rho g}{4\mu} [R^2 - r^2 + 2(R + \delta)^2 \ln \frac{r}{R}]$  ok.

So, if you plot the velocity profile it will look like this so; obviously,  $v$  will be 0 at the solid wall so, velocity will look like. Now, if we want to find the shear stress, then you can find  $\tau_{rz}$  inside the film thickness. So, shear stress  $\tau_{rz}$  you will get  $\mu \frac{dv_z}{dr}$  and this if you find you will get  $\frac{\rho g}{2} \left[ \frac{(R + \delta)^2}{r} - r \right]$  ok.

So; obviously, at  $r$  is equal to  $R + \delta$  you know that  $\tau_{rz}$  is equal to 0 and at  $r$  is equal to  $R$   $\tau_{rz}$  will be  $\frac{\rho g}{2} \left[ \frac{R^2 + 2\delta R + \delta^2}{R} - R \right]$ . So, if you put in this expression  $r$  is equal to  $R$ . So, you will get  $R^2 + 2\delta R + \delta^2 - R^2$ . So, this will get cancel so, you will get  $\frac{\rho g}{2} \frac{\delta}{R} (2R + \delta)$  ok. So, if you want to draw the shear stress profile

inside the fluid domain, then you will get the shear stress is 0 here right. So, it will vary like this.

(Refer Slide Time: 09:30)

### Film Flow Down a Vertical Cylinder

Volume flow rates

$$Q = \int_A v_z dA = \int_R^{R+\delta} 2\pi r v_z dr$$

$$= \frac{\pi P g}{2\mu} \int_R^{R+\delta} \left[ R^2 - r^2 + 2(R+\delta)^2 \ln \frac{r}{R} \right] r dr$$

$$\int r \ln \frac{r}{R} = \ln \frac{r}{R} \frac{r^2}{2} - \int \frac{r}{R} \cdot \frac{1}{R} \frac{r^2}{2} dr$$

$$= \frac{r^2}{2} \ln \frac{r}{R} - \frac{r^2}{4}$$

$$Q = \frac{\pi P g}{2\mu} \left[ R^2 \frac{r^2}{2} - \frac{r^4}{4} + 2(R+\delta)^2 \frac{r^2}{2} \ln \frac{r}{R} - 2(R+\delta)^2 \frac{r^2}{4} \right]_R^{R+\delta}$$

$$= \frac{\pi P g}{2\mu} \frac{R^4}{4} \left\{ 2 \left[ \left(1 + \frac{\delta}{R}\right)^2 - 1 \right] - \left[ \left(1 + \frac{\delta}{R}\right)^4 - 1 \right] + 4 \left(1 + \frac{\delta}{R}\right)^2 \ln \left(1 + \frac{\delta}{R}\right) - 2 \left(1 + \frac{\delta}{R}\right)^2 + 2 \left(1 + \frac{\delta}{R}\right)^2 \right\}$$

$$= \frac{\pi P g R^4}{8\mu} \left[ 4 \left(1 + \frac{\delta}{R}\right)^2 \ln \left(1 + \frac{\delta}{R}\right) - 1 + 4 \left(1 + \frac{\delta}{R}\right)^2 - 3 \left(1 + \frac{\delta}{R}\right)^4 \right]$$

$$= \frac{\pi P g R^4}{8\mu} \left[ 4 \left(1 + \frac{\delta}{R}\right)^2 \ln \left(1 + \frac{\delta}{R}\right) - \left\{ 4 \frac{\delta}{R} + 14 \left(\frac{\delta}{R}\right)^2 + 12 \left(\frac{\delta}{R}\right)^3 + 3 \left(\frac{\delta}{R}\right)^4 \right\} \right]$$

$dA = 2\pi r dr$

Now, we are interested to find the volume flow rate, and if volume flow rate is known then you can find the film thickness delta. So, first let us find what is the volume flow rate ok? So, if you want to calculate the volume flow rate, then you can write Q is equal to area integral v z d A.

So, in this particular case you can see that at a radius r, if you take a small elemental thickness d r, then this is the flow area ok. And the elemental area d A will be twice pi r into d r ok. So, if you put the velocity distribution v z here, and if you integrate it and the constant if you take so, it will be v z twice pi r d r and you have to integrate from R to R plus delta R to R plus delta.

So, here now you can see that it will be the constants you can take outside the integral,  $\pi \rho g$  by twice  $\mu R$  to  $R$  plus  $\Delta R^2$  minus  $r^2$  plus twice  $R$  plus  $\Delta^2$   $\ln r$  by  $R$  into  $r dr$ . So, now you multiply this  $r$  with these terms and integrate it so, you will get. So, first let us integrate this term integration by parts  $r$  into  $\ln r$  by  $R$  ok.

So, this is integration by parts you will get in the third term. So, this you can see you can write  $\ln r$  by  $R$ , then integral  $r dr$   $r^2$  by  $2$  minus integral. So, it will be  $dr$  by  $d \ln r$  by  $R$   $d$  of  $d \ln r$  by  $R$ . So, you will get  $R$  by  $r$  into  $1$  by  $R$ , then again integral  $r dr$  means  $r^2$  by  $2 dr$  ok.

So, these  $R R$  will get cancel here you will get  $1 R$ . So, you can write  $r^2$  by  $2 \ln r$  by  $R$  minus so, it will be again  $r^2$  by  $2$ . So, it will be  $r^2$  by  $4$  ok. Now, we can write this integral so,  $\pi \rho g$  by twice  $\mu$ . So, you can see first term it will be  $R^2$  into  $R$ . So, it will be  $R^2$  into  $r^2$  by  $2$  minus it will be  $r^3$ . So,  $r$  to the power  $4$  by  $4$  and plus  $2 R$  plus  $\Delta^2$  into integral  $r \ln r$  by  $R$ .

So, this is the term so, you can write  $r^2$  by  $2 \ln r$  by  $R$  minus  $2 R$  plus  $\Delta^2$   $r^2$  by  $4$  ok, and limits  $R$  to  $R$  plus  $\Delta$  ok. Now, if you put the limits you can see that it will be  $R$  plus  $\Delta$  whole square minus  $r^2$ . So, everywhere if you take  $\pi \rho g$  by twice  $\mu$ , you take  $R$  to the power  $4$  by  $4$  outside the bracket ok.

So, then you can write you can see it will be just so,  $2$  into  $1$  plus  $\Delta$  by  $R^2$  here, then minus  $1$  ok, because  $R^2$  will be there minus  $r^2$ , then minus so,  $R$  to the power  $4$  by  $4$  we have taken outside. So, it will be  $1$  plus  $\Delta$  by  $R$  to the power  $4$  minus  $1$ , then this term ok. So, it will be so,  $4$  we have taken outside. So, it will be plus  $4$   $1$  plus  $\Delta$  by  $R$  to the power  $4$  ok.

And we will get  $\ln 1$  plus  $\Delta$  by  $R$ , then minus  $2$   $1$  plus  $\Delta$  by  $R$  to the power  $4$  and one term will become  $0$  because it will be  $\ln 1$ . So,  $\ln 1$  is  $0$  so, this term we are not writing and you will get plus  $2$  into  $1$  plus  $\Delta$  by  $R$  whole square ok. So, if you put  $R$  then; obviously,  $R$  to the power  $4$  you are taking outside. So, it will be  $1$  plus  $\Delta$  by  $R$  whole square. So, if you

rearrange it so, you will get  $\pi \rho g R^4$  divided by  $8 \mu$ . So, you can see here  $2$  into  $1 + \Delta$  by  $R$  whole square right.

So, first let us take this term  $4$  into  $1 + \Delta$  by  $R$  to the power  $4$   $1 + \Delta$  by  $R$  ok. Then, here we have minus  $2$  and plus  $1$  so, it will be minus  $1$ , then we have  $4$  into  $1 + \Delta$  by  $R$  square. So, this is  $2$  into  $1 + \Delta$  by  $R$  whole square this term and this term. And now we have left with this term and this term.

So, you can see it will be minus  $3$   $1 + \Delta$  by  $R$  to the power  $4$ . So, after simplification you are going to get  $\pi \rho g R^4$  by  $8 \mu$   $4$   $1 + \Delta$  by  $R$  to the power  $4$   $1 + \Delta$  by  $R$  ok. And if you rearrange it then you can write as  $4 \Delta$  by  $R$  plus  $14 \Delta$  by  $R$  square plus  $12 \Delta$  by  $R$  cube plus  $3 \Delta$  by  $R$  to the power  $4$ .

So, you can see this is the expression for the volume flow rate of this film. Now, if  $Q$  is known then you will be able to find the film thickness  $\Delta$  from this expression. And if  $\Delta$  is known; obviously, the volume flow rate you will be able to find. Now, let us consider one limiting case ok, where film thickness is very very small compared to the radius of the cylinder.

(Refer Slide Time: 17:37)

**Film Flow Down a Vertical Cylinder**

Special Case:  
The annular film is very thin.

$$\frac{\delta}{R} \ll 1$$

$$\epsilon = \frac{\delta}{R} \quad \epsilon \ll 1$$

$$Q = \frac{\pi}{8\mu} \rho g R^4 \left[ 4(1+\epsilon)^4 \ln(1+\epsilon) - \{9\epsilon + 14\epsilon^2 + 12\epsilon^3 + 3\epsilon^4\} \right]$$

$$\ln(1+\epsilon) = \epsilon - \frac{\epsilon^2}{2} + \frac{\epsilon^3}{3} - \frac{\epsilon^4}{4} + O(\epsilon^5)$$

$$(1+\epsilon)^4 \ln(1+\epsilon) = (1+4\epsilon+6\epsilon^2+4\epsilon^3+\epsilon^4) \left[ \epsilon - \frac{\epsilon^2}{2} + \frac{\epsilon^3}{3} - \frac{\epsilon^4}{4} + O(\epsilon^5) \right]$$

$$= \epsilon + \frac{7}{2}\epsilon^2 + \frac{13}{3}\epsilon^3 + \frac{25}{12}\epsilon^4 + O(\epsilon^5)$$

$$Q = \frac{\pi}{8\mu} \rho g R^4 \left[ 4 \left\{ \epsilon + \frac{7}{2}\epsilon^2 + \frac{13}{3}\epsilon^3 + \frac{25}{12}\epsilon^4 + O(\epsilon^5) \right\} - \{9\epsilon + 14\epsilon^2 + 12\epsilon^3 + 3\epsilon^4\} \right]$$

$$= \frac{\pi}{8\mu} \rho g R^4 \left[ \frac{16}{3}\epsilon^3 + \frac{16}{3}\epsilon^4 + O(\epsilon^5) \right]$$

$$= \frac{\pi}{8\mu} \rho g R^4 \frac{16}{3} \left( \frac{\delta}{R} \right)^3$$

$$= \frac{2\pi}{3\mu} \rho g R \delta^3$$

So, special case where the annular film is very thin ok, and it can be approximated as a thin planar film ok. So, delta by R is much much smaller than 1 ok. So, now, let us define epsilon which is delta by R so; obviously, epsilon will be much much less than 1.

So, now if you express the volume flow rate in terms of epsilon, then we can write pi by 8 mu rho g R to the power 4, 4 into now delta by R we are putting epsilon, 1 n 1 plus epsilon minus 4 epsilon plus 14 epsilon square plus 12 epsilon cube plus 3 epsilon to the power 4 ok.

So, now let us expand this 1 n 1 plus epsilon ok. So, using Taylor series so, 1 n 1 plus epsilon ok, if you expand into Taylor series you are going to get epsilon minus epsilon square by 2 plus epsilon cube by 3 minus epsilon to the power 4 by 4 plus order of epsilon to the power 5.

So, we can write now  $1 + \epsilon$  to the power 4 this term we can write now  $1 + \epsilon$  plus  $\epsilon$  ok. So, this term if you write then you will get  $1 + 4\epsilon + 6\epsilon^2 + 4\epsilon^3 + \epsilon^4$  and these terms,  $\epsilon$  minus  $\epsilon^2$  plus  $2\epsilon^3$  minus  $\epsilon^4$  plus order of  $\epsilon$  to the power 5.

So, now if you multiply then you will get  $\epsilon + 7\epsilon^2 + 13\epsilon^3 + 25\epsilon^4 + \text{order of } \epsilon \text{ to the power } 5$ . So, now, if you see the volume flow rate  $Q$  so, this term you can put it here. So,  $\pi \cdot 8 \mu \rho g R$  to the power 4.

So, you have to multiply with  $4\epsilon + 7\epsilon^2 + 13\epsilon^3 + 25\epsilon^4 + \text{order of } \epsilon \text{ to the power } 5$ . And this term minus  $4\epsilon + 14\epsilon^2 + 12\epsilon^3 + 3\epsilon^4$  so, this is the term.

Now, if you rearrange it you will get  $\pi \cdot 8 \mu \rho g R$  to the power 4  $16\epsilon^3 + 16\epsilon^4 + \text{order of } \epsilon \text{ to the power } 5$ . So, you can see these will get cancelled, because you have  $4\epsilon$  here minus  $4\epsilon$  here. So, if you do the rearrangement you will get this term.

Now, in this case we have assumed that  $\epsilon$  is much much smaller than 1. So, you can neglect the higher order terms keeping only the first term ok, then you will get the volume flow rate, when you have a very thin film ok.

And that actually we will now we can write so, the first term you keep ok. And other terms you can neglect, neglect these terms only the first term if you keep, then you will get  $\pi \cdot 8 \mu \rho g R$  to the power 4  $16\epsilon^3$  and  $\epsilon$  is nothing, but  $\Delta R$  to the power 3. So, now you can see it will be  $2 \pi \cdot 3 \rho g R \Delta^3$  ok.

(Refer Slide Time: 22:22)

**Film Flow Down a Vertical Cylinder**

$$\frac{Q}{2\pi R} = \frac{\rho g \delta^3}{3\mu}$$
$$\frac{Q}{W} = \frac{\rho g \delta^3}{3\mu} \quad W = 2\pi R$$

*It can be approximated as a thin planar film.*

Now, if you rearrange it  $Q$  by twice  $\pi R$ , then you can write  $\rho g \delta^3$  by  $3\mu$  ok. So, you can see in this case if you consider twice  $\pi R$  which is actually the width  $W$ , then the volume flow rate per unit width you are getting the expression which actually we got it in Cartesian coordinate ok.

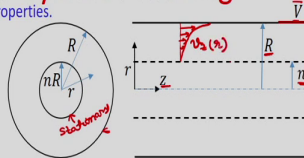

So, if film thickness is very very small compared to the  $R$ , you are going to get the volume flow rate same as what you got the thin film thickness in a vertical flat plate with the thin film. So, that results you are getting so; that means, it will be  $Q$  by  $W$   $\rho g \delta^3$  by  $3\mu$ , where  $W$  is equal to twice  $\pi R$ . So, you can see that it can be approximated as a thin planar film.

Now, let us consider the second problem ok. So, this is annular flow with the outer cylinder moving with a constant velocity  $V$ . So, in cylindrical coordinate you have 2 coaxial cylinders and the flow is taking place in the annulus.

(Refer Slide Time: 24:02)

**Annular Flow with the Outer Cylinder Moving**

Laminar, steady, incompressible fully-developed flow with constant fluid properties.  
 Two coaxial cylinders of infinite length.  
 The outer cylinder is steadily translated parallel to its axis with speed  $V$ .  
 The inner cylinder is fixed.  
 Pressure gradient and gravity are assumed to be negligible.

$$\text{G.E } \frac{d}{dr} \left( r \frac{dv_z}{dr} \right) = 0$$

$$r \frac{dv_z}{dr} = c_1$$

$$\frac{dv_z}{dr} = \frac{c_1}{r}$$

$$v_z(r) = c_1 \ln r + c_2$$

Boundary conditions:

$$\text{@ } r = nR, v_z = 0 \Rightarrow 0 = c_1 \ln(nR) + c_2$$

$$\text{@ } r = R, v_z = V \Rightarrow V = c_1 \ln(R) + c_2$$

$$c_1 = \frac{V}{\ln(1/n)} \quad c_2 = -V \frac{\ln(nR)}{\ln(1/n)}$$

Velocity distribution

$$v_z(r) = V \frac{\ln\left(\frac{r}{nR}\right)}{\ln(1/n)}$$

$\frac{r_i}{r_o} = \frac{nR}{R} = n$   
 $n < 1$

So, in this case you can see this is the inner cylinder of radius  $nR$  and outer cylinder is of radius  $R$ . And this outer cylinder is moving with a constant velocity  $V$  in the positive  $z$  direction ok, and inner cylinder is stationary. So, these are coaxial cylinders  $r$  is measured from the central line. So, you can see this is this cylinder is stationary, and this cylinder is moving with a constant velocity  $V$ .

And we are assuming laminar steady incompressible fully developed flow with constant fluid properties. And 2 coaxial cylinders of infinite length the outer cylinder is steadily translated

parallel to its axis with speed  $V$ , inner cylinder is fixed and pressure gradient and gravity are assumed to be negligible.

So, you can see that it is a purely shear driven flow ok. So, because pressure gradient is 0 and; obviously, gravity is 0 then it is a purely shear driven flow. So, now first we will derive the velocity distribution, then the volume flow rate and then with limiting case will see that what happens if the inner cylinder is not there and, if the inner cylinder radius is almost close to the outer cylinder radius.

So, first let us start with the governing equation so; obviously, pressure gradient is 0 gravity is 0. So, you can write the equation as  $\frac{d}{dr} r \frac{dv_z}{dr} = 0$ , if you integrate twice you will get the velocity profile and  $\frac{dv_z}{dr} = c_1 \frac{1}{r}$  and  $v_z$  which is function of  $r$  only you will get  $c_1 \ln r + c_2$  and what are the boundary conditions, boundary conditions are at  $r = R$  ok.

So, you can see in this case inner cylinder radius divided by outer cylinder radius is  $\frac{nR}{R}$  that means,  $n$  so,  $n$  obviously is less than 1 ok. So, at  $r = nR$   $v_z = 0$  so; that means, you will get  $0 = c_1 \ln nR + c_2$  and at  $r = R$ . That means, outer cylinder it is moving with a constant velocity  $V$ . So, it will get  $V = c_1 \ln R + c_2$ .

So, if you solve for this constants you get  $c_1 = \frac{V}{\ln R - \ln nR}$  and  $c_2 = -\frac{V \ln R}{\ln R - \ln nR}$ . So, if you put this constants in the velocity distribution, you will get  $v_z = \frac{V \ln r}{\ln R - \ln nR}$  ok.

So, this is the velocity distribution ok. So, how the velocity profile will look like. So, velocity profile will look like. So, you can see it is a purely shear driven flow velocity is 0 here, and you have velocity  $V$  at the outer cylinder ok. So, this is  $v_z$  which is function of  $r$ .

(Refer Slide Time: 28:15)

### Annular Flow with the Outer Cylinder Moving

Shear stress,

$$\tau_{rz} = \mu \frac{dv_z}{dr}$$

$$= \frac{\mu}{r} \frac{V}{\ln(r/R)}$$

@  $r = nR$ ,  $\tau_{rz} = \frac{\mu}{nR} \frac{V}{\ln(1/n)}$

@  $r = R$ ,  $\tau_{rz} = \frac{\mu}{R} \frac{V}{\ln(1/n)}$

Now, let us calculate the shear stress distribution. So, shear stress  $\tau_{rz}$  you can write as  $\mu \frac{dv_z}{dr}$ . So, from here you can write  $\mu \frac{V}{r \ln(r/R)}$ . So, at  $r = nR$   $\tau_{rz}$  will be just  $\mu \frac{V}{nR \ln(1/n)}$  and at  $r = R$   $\tau_{rz}$  will be  $\mu \frac{V}{R \ln(1/n)}$ .

So, if you draw the shear stress distribution; obviously, you can see that shear stress will be more in the inner cylinder. So, you will get  $\tau_{rz}$  ok.

(Refer Slide Time: 29:17)

**Annular Flow with the Outer Cylinder Moving**

Volume flow rate,

$$Q = \int_A v_z dA = \int_{nR}^R v_z 2\pi r dr$$

$$= \frac{2\pi V}{\ln(V/n)} \int_{nR}^R \ln\left(\frac{r}{nR}\right) r dr$$

$$\int \ln\left(\frac{r}{nR}\right) r = \ln\left(\frac{r}{nR}\right) \frac{r^2}{2} - \int \frac{dr}{r} \cdot \frac{1}{2nR} \frac{r^2}{2} dr$$

$$= \frac{r^2}{2} \ln\left(\frac{r}{nR}\right) - \frac{r^2}{4}$$

$$Q = \frac{2\pi V}{\ln(V/n)} \left[ \frac{r^2}{2} \ln\left(\frac{r}{nR}\right) - \frac{r^2}{4} \right]_{nR}^R$$

$$= \frac{2\pi V}{\ln(V/n)} \left[ \frac{R^2}{2} \ln\left(\frac{1}{n}\right) - \frac{n^2 R^2}{2} \ln 1 - \frac{R^2}{4} + \frac{n^2 R^2}{4} \right]$$

$$= \frac{2\pi V}{\ln(V/n)} \frac{R^2}{4} \left[ 2 \ln\left(\frac{1}{n}\right) - 1 + n^2 \right]$$

$$= \frac{\pi V R^2}{2} \left[ 2 + \frac{n^2 - 1}{\ln\left(\frac{1}{n}\right)} \right]$$

$dA = 2\pi r dr$

Now, we are interested to find the volume flow rate. So, volume flow rate you can find  $Q$  as area integral  $v_z dA$  and obviously, in this case you can see here  $dA$  will be twice  $\pi r dr$ . So, it will be integral so,  $nR$  to  $R$   $v_z$  twice  $\pi r dr$ .

So, now you put the expression of  $v_z$  here and take the constant outside the integral, then you can write twice  $\pi V$  divided by  $\ln(V/n)$  by  $\int_{nR}^R \ln\left(\frac{r}{nR}\right) r dr$ . So, again if you use the integration by parts, then you can find  $\ln\left(\frac{r}{nR}\right) r$  as so, it will be  $\ln\left(\frac{r}{nR}\right) r$  minus  $\int \frac{1}{r} \cdot \frac{r^2}{2nR} dr$ . Now, you can see here you will get  $\frac{r^2}{2} \ln\left(\frac{r}{nR}\right) - \frac{r^2}{4}$ .

So, it will be  $\frac{R^2}{2} \ln\left(\frac{1}{n}\right) - \frac{n^2 R^2}{2} \ln 1 - \frac{R^2}{4} + \frac{n^2 R^2}{4}$ . So, it will be  $\frac{R^2}{4} \left[ 2 \ln\left(\frac{1}{n}\right) - 1 + n^2 \right]$ . So, it will be  $\frac{\pi V R^2}{2} \left[ 2 + \frac{n^2 - 1}{\ln\left(\frac{1}{n}\right)} \right]$ .

So, if you put it here then you are going to get twice pi V divided by 1 n 1 by n. So, it will be r square by 2 1 n r by n R minus r square by 4 n R to R. So, if you put the limits you will get you see R square by 2 1 n 1 by n minus n square R square by 2 1 n 1 and 1 n 1 this will be 0 and minus R square by 4 and plus n square R square by 4 ok.

So, if you rearrange it if you take outside R square by 4, then it will be twice pi V divided by 1 n 1 by n R square by 4, if you take outside. So, you will get 2 1 n 1 by n minus 1 plus n square. So, finally, you can write pi V R square divided by 2 into if you this denominator, whatever it is there if you take inside the bracket, then it will be 2 plus n square minus 1 divided by 1 n 1 by n. Now, we will discuss 2 special cases where n tends to 0 and n tends to 1.

**Annular Flow with the Outer Cylinder Moving**

Special Cases:

$$v_z = \lim_{n \rightarrow 0} V \frac{\ln\left(\frac{r_2}{nr}\right)}{\ln(V/n)}$$

$$= \lim_{n \rightarrow 0} V \frac{\ln\left(\frac{r_2}{nr}\right) + \ln\left(\frac{r_2}{r}\right)}{\ln\left(\frac{r_2}{nr}\right) + \ln\left(\frac{r_2}{r}\right)}$$

$$= V \lim_{n \rightarrow 0} \left[ 1 + \frac{\ln\left(\frac{r_2}{r}\right)}{\ln\left(\frac{r_2}{nr}\right)} \right]$$

$$= V$$

$\lim_{n \rightarrow 0} \frac{\ln\left(\frac{r_2}{r}\right)}{\ln\left(\frac{r_2}{nr}\right)} \rightarrow 0$

The annular flow degenerates to flow in a tube.

$$Q = \frac{\pi V R^2}{2} \left[ 2 + \frac{n^2 - 1}{\ln(V/n)} \right]$$

$$Q = \frac{\pi V R^2}{2} \lim_{n \rightarrow 0} \left[ 2 + \frac{n^2 - 1}{\ln\left(\frac{r_2}{nr}\right)} \right]$$

$$Q = \frac{\pi V R^2}{2} \cdot 2 = V \pi R^2 \quad A = \pi R^2$$

So, special cases first we will consider n tends to 0 ok. So, what will happen? So, if n tends to 0 then you can write v z is equal to limit n tends to 0 so, velocity you know V 1 n r by n R

divided by  $1/n$  by  $n$  ok. So, this you can write limit  $n$  tends to  $0$   $V$  so, this term you can write as  $1/n$  plus  $1/n$  by  $R$  divided by  $1/n$  by  $n$ .

So, you can see you can write limit  $n$  tends to  $0$ ,  $V$  you can take it outside because it is constant. So, it will be  $1$  plus  $1/n$  by  $R$   $1/n$  by  $n$  ok. So, if  $n$  tends to  $0$  so you can see this will become  $1/n$  infinity right. And  $1/n$  infinity is infinity so,  $1$  by infinity will become  $0$ . So, you can write this equal to  $V$  ok, because as  $n$  tends to  $0$  this second term will become  $0$  ok. So, limit  $n$  tends to  $0$   $1/n$  by  $R$  divided by  $1/n$  by  $n$  this tends to  $0$  ok.

So, what is this flow, what is this flow? You can see that the fluid inside will have the same velocity which is having the magnitude  $V$  so; that means, it is a plug flow right. So, the annular flow degenerates to flow in a tube ok. So, this is a solid body translation you can see. Now, whatever the volume flow rate so, volume flow rate we have already calculated as  $Q$  is equal to  $\pi V R^2$  plus  $n^2$  minus  $1$  divided by  $1/n$  by  $n$  ok.

So, you can see so  $Q$  when limit  $n$  tends to  $0$   $n$  tends to  $0$   $2$  plus  $n^2$  minus  $1$  by  $1/n$  by  $n$ . So,  $1/n$  by  $n$  will become infinity so, this second term will become  $0$ . So,  $Q$  will be just  $\pi V R^2$  into  $2$ . So, what is that that will be  $V$  into  $\pi R^2$  and  $\pi R^2$  is nothing, but the flow area right flow area is  $\pi R^2$ .

So, in this case for the plug flow, you can see that the flow area is; obviously,  $\pi R^2$  and uniform velocity you have inside that is  $V$ . So, volume flow rate will be just  $V$  into  $A$ ; that means,  $V$  into  $\pi R^2$  and that we have already shown. Now, let us consider the other limiting case where  $n$  tends to  $1$  so; that means, the inner cylinder radius will come closer to the outer cylinder radius ok.

(Refer Slide Time: 37:17)

**Annular Flow with the Outer Cylinder Moving**

Special Case:

$n \rightarrow 1$ .  $\epsilon = \frac{1}{n} - 1 \Rightarrow \epsilon = \frac{1-n}{n} \Rightarrow \frac{1}{n} = 1 + \epsilon$   
 $n \rightarrow 1, \epsilon \rightarrow 0$

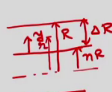

$\Delta R = R - nR = (1-n)R = n\epsilon R$   
 $\Rightarrow nR = \frac{\Delta R}{\epsilon}$

Cartesian coordinates,  $(y, z)$

$y = z - nR$   
 $\Rightarrow \frac{y}{nR} = 1 + \frac{z}{nR} = 1 + \epsilon \frac{z}{\Delta R}$

$v_z(r) = V \frac{\ln\left(\frac{r}{nR}\right)}{\ln\left(\frac{1}{n}\right)}$   
 $v_z(r) = V \frac{\ln\left(1 + \epsilon \frac{z}{\Delta R}\right)}{\ln(1 + \epsilon)}$

Using L'Hospital's rule,  
 $v_z = \lim_{\epsilon \rightarrow 0} V \frac{\ln\left(1 + \epsilon \frac{z}{\Delta R}\right)}{\ln(1 + \epsilon)} = \lim_{\epsilon \rightarrow 0} V \cdot \frac{\frac{z}{\Delta R}}{1 + \epsilon} \frac{1 + \epsilon}{1 + \epsilon \frac{z}{\Delta R}}$   
 $v_z = V \frac{z}{\Delta R}$

So, another special case where  $n$  tends to 1 ok. So, now, we will show that these flow actually will become the plane Couette flow ok, which we have already done in Cartesian coordinate ok. So, you can see that let us define epsilon as  $1/n - 1$ . And you can see that  $n$  is less than 1 and; obviously, if  $n$  tends to 1, then as  $n$  tends to 1 epsilon will be tends to 0 ok.

So, now, let us define the delta  $R$  the difference between 2 radius is outer radius minus inner radius ok. So, it will be  $1 - n$  into  $R$  and from here, you can see epsilon is  $1/n - 1$  divided by  $n$ . So,  $1/n - 1$  you can write as  $n$  into epsilon into  $R$ . So, from here you can see  $nR$  we can write as  $\Delta R$  by epsilon ok. Now, you introduce the Cartesian coordinates ok.

So, with the origin on the surface of the inner cylinder so,  $y$  we are measuring. So,  $y$  we are measuring from here and this is  $R$  and this is  $nR$  and this is  $\Delta R$  ok. So, we can write so,  $n$  at any radial location  $R$  we can write  $y$  is equal to  $r - nR$  right  $r$  minus inner radius. So,

you can write  $r$  by  $n R$  is equal to  $1 + \frac{y}{n R}$  and  $\frac{y}{n R}$  is you can write so,  $n R$  is equal to  $\Delta R$  by  $\epsilon$ . So, you can write  $1 + \frac{\epsilon y}{\Delta R}$  ok.

So, now you substitute this  $r$  by  $n R$  this expression in the velocity distribution. So, what is your velocity distribution? So,  $v_z$  we have the  $V$  into  $1 + \frac{y}{n R}$  divided by  $1 + \frac{y}{n}$ . So, if you put in this expression then  $v_z$  you can write  $V$  into  $1 + \frac{y}{n}$ . So,  $r$  by  $n R$  now we are substituting  $1 + \frac{\epsilon y}{\Delta R}$  divided by  $1 + \frac{y}{n}$ . Now,  $1 + \frac{y}{n}$  so,  $1 + \frac{y}{n}$  you can see from here  $1 + \frac{y}{n}$  we can write  $1 + \frac{\epsilon y}{\Delta R}$  so,  $1 + \frac{y}{n}$  now you want to write  $1 + \frac{\epsilon y}{\Delta R}$ .

So, you can see now let us find when  $\epsilon$  tends to 0 ok. So, as  $\epsilon$  tends to 0, then we will use using L' Hospital's rule  $v_z$  we can write as limit  $\epsilon$  tends to 0  $V \frac{1 + \frac{\epsilon y}{\Delta R}}{1 + \frac{y}{n}}$  so, these if you write using L' Hospital's rule. So, you have to take the derivative of this denominator and numerator with respect to  $\epsilon$ .

So, you will get so, limit  $\epsilon$  tends to 0  $V \frac{y}{\Delta R} \frac{1}{1 + \frac{y}{n}}$  ok. Because, you can see so this will become  $1 + \frac{y}{n}$  by  $\Delta R$ . So, this you are getting and if you take this derivative, then  $y$  by  $\Delta R$  and in the denominator  $1 + \frac{y}{n}$  and it will come in the numerator.

So, now if  $\epsilon$  tends to 0 so, it will become this term will become 1 ok. So, you will get  $v_z$  is equal to  $V \frac{y}{\Delta R}$ . So, now, you can see that it is just the expression of velocity for plane Couette flow, where  $\Delta R$  is the distance between 2 flat plates ok. So, that is we considered earlier case as  $H$  and it is varying linearly with  $y$  ok

(Refer Slide Time: 43:00)

Annular Flow with the Outer Cylinder Moving

$$v_z = V \frac{y}{\Delta R}$$

Plane Couette flow,  $u = V \frac{y}{H}$   
 $H = \Delta R$

We obtain a linear velocity distribution which corresponds to plane Couette flow between plates separated by a distance  $\Delta R$ .

So,  $v_z$  is equal to  $V$  into  $y$  by  $\Delta R$ . So, for plane Couette flow we calculated  $u$  as  $V$  into  $y$  by  $H$  if you remember ok. So,  $H$  is the distance between 2 plates. So,  $H$  is equivalent to  $\Delta R$  ok. So, we are getting the linear velocity profile ok. So, we obtain a linear velocity distribution which corresponds to plane Couette flow between plates separated by a distance  $\Delta R$ . So, in today's class first we considered the liquid flowing outside a cylinder surface in the downward direction.

So, assuming surface tension 0 we considered uniform film thickness  $\Delta$ . So, for this particular case we can see that as outer ambient air is stationary. And they are; obviously, you have the ambient pressure as atmospheric pressure so; obviously, there will be no pressure gradient in the  $z$  direction.

So,  $\frac{\partial p}{\partial z}$  is equal to 0 and we have only gravity driven flow and for that we express the velocity distribution in terms of  $R$ . Then, we calculated the volume flow rate and we considered a special case where  $\frac{\Delta}{R}$  is very very small; that means, you have a thin film thickness which is very thin. So, in this particular case this actually degenerates to a thin film flow in a Cartesian coordinate.

Next we considered flow inside 2 coaxial cylinders where outer cylinder is moving with a constant velocity  $V$  and inner cylinder is stationary. So, in this particular case we calculated the velocity distribution, as well as the volume flow rate and two special cases we considered 1 is  $n$  tends to 0; that means, inner cylinder is removed. So; obviously, this degenerates to a plug flow where you have a uniform velocity  $V$  and we have also shown that the volume flow rate will become just  $V$  into the area which is  $\pi R^2$ .

Then the special case we considered where  $n$  tends to 1; that means, this inner cylinder is coming closer to the outer cylinder. So, we defined the  $\Delta R$  which is the thickness between these two cylinders that is as outer radius minus the inner radius. And, we defined one small thickness  $\epsilon$  which is much much smaller than 1 ok.

So, in this particular case now we have seen that when  $\epsilon$  tends to 0 this flow actually degenerates to plane Couette flow in Cartesian coordinate and the velocity profile becomes linear.

Thank you.
