Laminar Free Shear Flows
Lecture - 01
Two-dimensional Laminar Jet

Hello everyone. So, till now we have considered wall bounded flows where we have considered boundary layer flow over a flat plate, then flow over a circular cylinder. But today, we will consider Free Shear Flows and also we will assume laminar and incompressible fluid flow.

(Refer Slide Time: 00:57)

Self-similar Solution of Free Shear Flows

Free shear flow is the unbounded region of a large body of fluid, which have either excess momentum (ex. jet and plume) or momentum deficit (ex. wake).

BL equations:

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$$
$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2}$$

Assumptions:

- i) large Re flow
- ii) $\frac{\partial p}{\partial x} = 0$
- iii) $\frac{\partial p}{\partial y} = 0$
- iv) $v \ll u$

Free shear flow is the unbounded region of a large body of fluid which have either excess momentum examples are jet and plume or momentum deficit like wake. So, whatever governing equation we have derive for laminar boundary layer flows, if dominant velocity is in the x direction then those equations are valid for free shear flows. So, let us write down the governing equations.

So, we can have $\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$. So, this is the continuity equation and the boundary layer equation we can have as $u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2}$. So; obviously, we are considering that

dominant free shear velocity is u in the x direction. So, obviously, if you can see that these are the assumptions we have made.

So, one is large Reynolds number flows ok then boundary layer theory is valid and no separation then we are having $\frac{\partial p}{\partial y}$ is equal to 0 and also it is open to the atmosphere and we can have the assumptions of $\frac{\partial p}{\partial x}$ is equal to 0 and also we have v velocity is much much smaller than u so; obviously. So, these are the boundary layer equations.

(Refer Slide Time: 03:00)

Two-dimensional Laminar Jet

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$$

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2}$$

Boundary Conditions:

@ $y=0$, $\frac{\partial u}{\partial y} = 0$, $v=0$

@ $y \rightarrow \infty$ $u \rightarrow 0$, $v=0$, $\frac{\partial u}{\partial y} = 0$

$$\frac{\partial(uv)}{\partial x} + \frac{\partial(uv)}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2}$$

$$\frac{d}{dx} \int_{-\infty}^{+\infty} u^2 dy + [uv]_{-\infty}^{+\infty} = \nu \frac{\partial u}{\partial y} \Big|_{-\infty}^{+\infty}$$

$$\frac{d}{dx} \int_{-\infty}^{+\infty} u^2 dy = 0$$

So that $\int_{-\infty}^{+\infty} u^2 dy = \text{constant} = \frac{J}{\rho}$

$$J = \int_{-\infty}^{+\infty} \rho u^2 dy = \text{constant}$$

So, now we will consider two dimensional laminar jet and we will use similarity transformation technique to find the velocity distribution in the two dimensional laminar jet. So, consider this is the laminar jet and this is the small opening of height h and this is known as slit. When at high velocity this fluid will enter. So, there will be formation of jet and there will be center line.

So, you can see that this is the jet boundary and there will be some fluid entrainment from here fluid entrainment from the jet boundary. So, physically jet spreads in outward direction with increasing x going to momentum diffusion due to viscosity and the velocity in the center line will decrease. So, you can see that we have considered two x location say let us say this is your location x_1 and location x_2 . So, center line velocity will decrease as well as it will spread in outward direction.

So, if we neglect the fluid entrainment from the jet boundary then we can solve these governing equations easily. So, we have the governing equation continuity equation $\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$ and $u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2}$. So, what are the boundary conditions for this case?

So, we are taking the axial direction is x along the center line and it is symmetric about the center line and this is the y direction. So, you can see that boundary conditions we have at $y = 0$ we will have maximum velocity; that means, it is symmetric line. So, we can have $\frac{\partial u}{\partial y} = 0$ as well as velocity $v = 0$ and as y tends to infinity; that means, far away you can see that velocity will be tending to 0.

So, u velocity will be tending to 0. This equation if you write in conservative form then we can write $\frac{\partial}{\partial x} (u^2) + \frac{\partial}{\partial y} (uv) = \nu \frac{\partial^2 u}{\partial y^2}$. So, this is the conservative form of this momentum equation now if you integrate it from $y = -\infty$ to $y = +\infty$ at a particular x location then we can write as d of dx .

So, if you use Leibnitz theorem and you can convert it to $-\infty$ to $+\infty$ $u^2 dy$ and this if you integrate then it will be just u^2 $-\infty$ to $+\infty$ and is equal to $\nu \frac{\partial u}{\partial y} \Big|_{-\infty}^{+\infty}$. So, you can see that at y tends to infinity v also is 0. So, you can see that as y plus minus infinity will have u^2 are 0.

So obviously, this term will become 0. So, this is 0 ok and you can see that at y tends to infinity obviously, we will have $\frac{\partial u}{\partial y} = 0$ because u is 0 right there will be no velocity gradient outside this z boundary. So, $\frac{\partial u}{\partial y}$ also will be 0. So, this is also 0. So, from here you can see that we can write d of dx integral $-\infty$ to $+\infty$ $u^2 dy$ is equal to 0.

So, if you integrate it. So, you can see that we can write so, that $-\infty$ to $+\infty$ $u^2 dy$ is equal to constant ok constant and if you see the total flux of x momentum integrated on y at any location x , then we can get J is equal to integral $-\infty$ to $+\infty$ $\rho u^2 dy$. So, you can see that for incompressible flow ρ is constant.

So, you can take it outside. So, you can see that it will become J by ρ ; that means, J which is your momentum flux at any location x is constant. So, this is one important property ok. So, this is one important property where in the solution we will use that J which is your momentum flux in at any location x .

So, J , J is the momentum flux you can see that it is independent of x . So, it is constant at any station of x location. So, this is constant. So, we will use the similarity transformation technique to find the solution of this jet flow.

(Refer Slide Time: 09:14)

Two-dimensional Laminar Jet

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2}$$

self-similar solution:

$$\psi \sim x^p f(\eta) \quad \eta \sim \frac{y}{x^q}$$

where x^p sets the scale of the jet thickness at a given x
 x^q scaling in y direction.

$$\psi = A x^p f \quad \eta = \frac{y}{B x^q}$$

BCs: @ $\eta = 0$, $f = 0$, $f'' = 0$,
 @ $\eta \rightarrow \infty$, $f' = 0$.

So, we will use the governing equation as $u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y}$ is equal to $\nu \frac{\partial^2 u}{\partial y^2}$. So, we will use the self-similar solution. So, when can we use self-similar solution? So, if you see that any location x whatever velocity distribution you will get that those are varying only with a scale factor ok. So, if you use some suitable transformation variable then all the velocity profiles will fall in single curve.

So, that is the self-similar solution. So, for this we can have the self-similar solution and we will use this similarity variable ψ as varies as x to the power p $f(\eta)$ where η is the similarity variable y by x to the power q and where x to the power p sets the scale of the jet thickness at a given x and x to the power q is the scaling in the y direction.

So, we can use that ψ is equal to some constant $A x$ to the power p f which is function of η and η is y by B into x to the power q . So, A B we will be choose in such a way

that f and η will be dimensionless. So, what are the boundary conditions in terms of f ? So, you can see that boundary conditions at η is equal to 0 so; obviously, at η is equal to 0 we can say that ψ will be 0 and so, at y is equal to 0. So, one y is equal to 0.

So, we can have the symmetry line and ψ will be constant. So, f will be 0 ok. So, for convenience we are taking this and f'' will be also 0 ok at η is equal to 0 at η tends to infinity.

So, velocity will be 0. So, f' will be 0. So, $f'' = 0$; that means, the velocity gradient $\frac{\partial u}{\partial y}$ will be 0 because we are having maximum velocity at the center line. So, now we have defined the stream function ψ and the similarity variable η now let us use the momentum equation and write it in terms of the stream function ψ .

(Refer Slide Time: 12:26)

Two-dimensional Laminar Jet

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2}$$

$$\psi = A x^p f \quad \eta = \frac{y}{B x^q} \quad \frac{\partial \eta}{\partial x} = \frac{y}{B} (-q) x^{-q-1} = -\frac{q y}{B x^{q+1}}$$

$$\frac{\partial \psi}{\partial x} = A x^p f' \frac{1}{B x^q} = \frac{A}{B} f' x^{p-q}$$

$$\frac{\partial u}{\partial x} = \frac{A}{B} \left[(p-q) x^{p-q-1} f' - x^{p-q} f'' \frac{q y}{B x^{q+1}} \right]$$

$$\frac{\partial u}{\partial x} = \frac{A}{B} \left[(p-q) x^{p-q-1} f' - x^{p-q} f'' \eta \frac{q}{x} \right]$$

$$v = -\frac{\partial \psi}{\partial x} = - \left[A p x^{p-1} f + A x^p f' \left(-\frac{q y}{B x^{q+1}} \right) \right]$$

$$\Rightarrow v = - \left[A p x^{p-1} f - A x^p f' \eta \frac{q}{x} \right]$$

$$\frac{\partial u}{\partial y} = \frac{A}{B} x^{p-q} f'' \frac{1}{B x^q} = \frac{A}{B^2} x^{p-2q} f''$$

$$\frac{\partial^2 u}{\partial y^2} = \frac{A}{B^2} x^{p-2q} f''' \frac{1}{B x^q} = \frac{A}{B^3} x^{p-3q} f'''$$

So, we have the momentum equation $u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2}$ and we have defined ψ as $A x^p f$ where f is function of η and η is y by $B x^q$. So, from here you can see you can write $\frac{\partial \eta}{\partial y}$ is equal to $\frac{1}{B x^q}$ and $\frac{\partial \eta}{\partial x}$ we can write as $-\frac{q y}{B x^{q+1}}$.

So, x to the power $p-q$. So, $p-q$ and x to the power $p-q-1$. So, you can write it as $(p-q) x^{p-q-1} f'$ ok. Now let us find the velocity u as $\frac{\partial \psi}{\partial x}$. So, from here you can see that we can write $A x^p f' \frac{1}{B x^q}$

by $\frac{\partial \eta}{\partial y}$. So, you can write f' and $\frac{\partial \eta}{\partial y}$. So, $\frac{\partial \eta}{\partial y}$ is 1 by $B x^q$.

Then we can write $\frac{\partial u}{\partial x}$. So, you can see this is your u . So, you can write $\frac{\partial u}{\partial x}$. So, A by B you can take it outside the bracket. So, this we can write as A by $B f'$ x to the power $p - q$. So, $\frac{\partial u}{\partial x}$ if we write then it will be $p - q$ x to the power $p - q - 1$, f' then we can have x to the power $p - q$ f'' then $\frac{\partial \eta}{\partial x}$.

So, $\frac{\partial \eta}{\partial x}$ is $-q y$ by B 1 by x to the power $q + 1$. So, that is why we have written minus sign here then we can write $q y$ by $B x$ to the power $q + 1$. So, if you simplify it then we will get $\frac{\partial u}{\partial x}$ as A by B $p - q$ x to the power $p - q - 1$ f' minus. So, you can see here y by $B x$ to the power q we can write as η .

So, we can write x to the power $p - q$ f'' η q by x . Now we can write v , v as $-\frac{\partial \psi}{\partial x}$ ok. So, v is equal to $-\frac{\partial \psi}{\partial x}$. So, from here you can see that we can write minus. So, $\frac{\partial \psi}{\partial x}$. So, it will be A p x to the power $p - 1$ f' then plus A x to the power p f' then $\frac{\partial \eta}{\partial x}$.

So, $\frac{\partial \eta}{\partial x}$ is this one $-q y$ by $B x$ to the power $q + 1$. So, if you simplify it you will get v is equal to $-A$ p x to the power $p - 1$ f' minus A x to the power p f' η q by x then let us find $\frac{\partial u}{\partial y}$. So, $\frac{\partial u}{\partial y}$ ok. So, this is your u . So, from here $\frac{\partial u}{\partial y}$ if you find.

So, it will be A by $B x$ to the power $p - q$ f'' and $\frac{\partial \eta}{\partial y}$ $\frac{\partial \eta}{\partial y}$ is 1 by $B x$ to the power q . So, if you simplify it you will get A by $B^2 x$ to the power $p - 2q$ f'' and now let us find this one. So, $\frac{\partial^2 u}{\partial y^2}$ is equal to. So, you take derivative with respect to y . So, it will be A by $B^2 x$ to the power $p - 2q$ f''' .

Then $\frac{\partial \eta}{\partial y}$; that means, 1 by $B x$ to the power q . So, you will get A by $B^3 x$ to the power $p - 3q$ f''' . Now we have evaluated the velocities u v and the other gradient. So, now, let us put it in the momentum equation.

(Refer Slide Time: 17:28)

Two-dimensional Laminar Jet

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2}$$

$$\frac{A}{B} x^{p-q} f' \frac{A}{B} [(p-q) x^{p-q-1} f' - x^{p-q} f'' \eta \frac{q}{x}]$$

$$+ [A p x^{p-1} f - A x^p f' \eta \frac{q}{x}] \frac{A}{B^2} x^{p-2q} f''$$

$$= \nu \frac{A}{B^3} x^{p-3q} f'''$$

$$\Rightarrow \frac{AB}{\nu} x^{p+q-1} [(p-q) f'^2 - p f f''] = f''' \leftarrow$$

For similarity, $p+q-1=0$
 $\therefore p+q=1$

Again, $J = \rho u_0^2 h = \rho \int_{-\infty}^{+\infty} u^2 dy$ $\eta = \frac{y}{B x^q}$
 $= \rho \int_{-\infty}^{+\infty} \frac{A^2}{B^2} x^{2p-2q} f'^2 B x^q d\eta$ $dy = B x^q d\eta$
 $= \rho \frac{A^2}{B} x^{2p-2q} \int_{-\infty}^{+\infty} f'^2 d\eta$
 $2p-2q=0 \Rightarrow p=\frac{1}{3}, q=\frac{2}{3}$

So, we have equation $u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y}$ is equal to $\nu \frac{\partial^2 u}{\partial y^2}$. So, now, let us put all the values. So, if you put it we have written u as $\frac{A}{B} x^{p-q} f'$ to the power p minus q f' $\frac{\partial u}{\partial x}$ $\frac{A}{B} [p x^{p-1} f' - x^p f'' \eta \frac{q}{x}]$ $\frac{A}{B^2} x^{p-2q} f''$ minus $\nu \frac{A}{B^3} x^{p-3q} f'''$.

Then we have v . So, v as $A p x^{p-1} f - A x^p f' \eta \frac{q}{x}$ then we have $\frac{\partial u}{\partial y}$. So, it will be $\frac{A}{B^2} x^{p-2q} f''$ and right hand side we have $\frac{\partial^2 u}{\partial y^2}$. So, it will be $\frac{A}{B^3} x^{p-3q} f'''$. If you simplify it you will get $\frac{AB}{\nu} x^{p+q-1} [p x^{p-1} f' - x^p f'' \eta \frac{q}{x}] \frac{A}{B^2} x^{p-2q} f'' = \frac{A}{B^3} x^{p-3q} f'''$.

So, if you see this equation. So, we use the self-similar solution and we assume that self-similar solution exist for this flow then; obviously, this equation should be independent of x and to make it independent of x you can see the this power $p+q-1$ must be 0. So, for similarity $p+q-1$ should be 0 that means, $p+q$ is equal to 1 and also we know J is equal to $\rho u_0^2 h$ where u_0 is the inlet velocity is equal to $\rho \int_{-\infty}^{+\infty} u^2 dy$.

So, J is equal to we can write u^2 we know this is $\int_{-\infty}^{+\infty} \frac{A^2}{B^2} x^{2p-2q} f'^2 B x^q d\eta$. So, $dy = B x^q d\eta$.

we have eta is equal to y by B x to the power q. So, dy you can write B x to the power q d eta. So, it will be B x to the power q d eta.

So, if you see this we can write it as rho A square by B x to the power twice p minus q this we can take it outside because we are integrating with respect to eta it will be minus infinity to plus infinity f prime square d eta. So, this J as we have shown that it will be constant right. So, to make it constant this power of x must be 0.

So, you can see that it will be constant for all x if twice p minus q is 0. So; that means, twice p minus q is equal to 0 ok. So, we have p plus q is equal to 1 and twice p minus q is equal to 0 that will give you p is equal to 1 by 3 and q is equal to 2 by 3.

(Refer Slide Time: 21:51)

Two-dimensional Laminar Jet

$$\frac{AB}{3\nu} x^0 \left[\left(\frac{1}{3} - \frac{2}{3}\right) f'^2 - \frac{1}{3} f f'' \right] = f'''$$

$$\Rightarrow f''' + \frac{AB}{3\nu} [f'^2 + f f''] = 0$$

BCs. $f'(\infty) = 0, f''(0) = 0$
 $v_y = 0, v = 0, f(0) = 0$

$$f''' + \frac{AB}{3\nu} \frac{d}{d\eta} (f f') = 0$$

Integrating,

$$f'' + \frac{AB}{3\nu} f f' = c$$

$$f(0) = f''(0) = 0$$

$$\Rightarrow c = 0$$

$$\therefore f'' + \frac{AB}{3\nu} f f' = 0$$

For convenience, $A = \left(\frac{3\nu J}{2\rho}\right)^{1/3}$ $B = \left(\frac{48\nu^2\rho}{J}\right)^{1/3}$

$$\frac{AB}{3\nu} = 2$$

So, now, if you put p and q value in this equation then we will get AB by nu. So, x to the power 0 1 by 3 minus 2 by 3 f prime square minus 1 by 3 f f double prime is equal to f triple prime. So, further if you simplify we will get f triple prime plus AB by 3 nu f prime square plus f f double prime is equal to 0.

So, with the boundary conditions f prime at infinity ok that is the velocity is 0 and f double prime; that means, the velocity gradient at center line is 0 and v is also 0 right at y is equal to 0 v is equal to 0. So, from here you will get that the stream function will be constant at the centre line. So, and that we are making as 0.

So, $f(0)$ is 0. So, now, you can see that this equation we can rewrite as $f''' + 2ff'' = 0$. If we integrate it we can write after integrating $f'' + \frac{d}{d\eta}(f^2) = 0$ ok. So, we have the boundary conditions that f at η is equal to 0 and f'' at η is equal to 0 is 0. So, that will give c is equal to 0.

So, we will get the equation finally, $f'' + 2ff' = 0$. So, now, you can see that in this equation these AB are present and to have this f and η as dimensionless we have to choose the value of AB such way that f and η will become dimensionless.

So, for convenience let us choose the value of A as $9\nu J$ divided by 2ρ to the power $1/3$ and B as $48\nu^2\rho$ divided by J to the power $1/3$ ok. So, if you choose that then the solution will also become easy. So, from here you can see AB if you calculate it will become 2 ok.

(Refer Slide Time: 25:01)

Two-dimensional Laminar Jet

$$f'' + 2ff' = 0$$

$$\text{or } f'' + \frac{d}{d\eta}(f^2) = 0$$

Integrating,

$$f' + f^2 = c$$

$$\text{at } \eta = 0, f(0) = 0 \quad f' = \frac{u}{u_{\text{max}}} \Big|_{\eta=0} = 1$$

$$\Rightarrow c = 1$$

$$\therefore f' + f^2 = 1$$

$$\Rightarrow \frac{df}{d\eta} = 1 - f^2$$

$$\Rightarrow \frac{df}{1-f^2} = d\eta$$

Integrating,

$$\tanh^{-1} f = \eta$$

$$\Rightarrow f = \tanh \eta$$

So, the equation this equation now, will become $f'' + 2ff' = 0$. Again we can write $f'' + \frac{d}{d\eta}(f^2) = 0$ this we can rewrite like this. So, now integrating we will get $f' + f^2 = \text{constant}$.

So, you can see at eta is equal to 0 we have f is 0 and f prime we are defining as u by u max at eta is equal to 0 ok. So, f prime at eta is equal to 0 ok because maximum velocity will occur at center line. So, this will be 1 so that means, c will become 1. So, we can write f prime plus f square is equal to 1 we can write then this is df by d eta. So, d f by d eta is equal to 1 minus f square.

So, you can write d f divided by 1 minus f square is equal to d eta. So, integrating we will get tan hyperbolic inverse f is equal to eta ok so that means, f will become tan hyperbolic eta. So, what is the physical significance of f? So, f is having the physical significance of stream function and f prime is the velocity.

(Refer Slide Time: 26:52)

Two-dimensional Laminar Jet

The corresponding velocity profiles are

$$\frac{u}{u_{max}} = f' = 1 - f^2 = 1 - \tanh^2 \eta = \operatorname{sech}^2 \eta$$

$$u = \frac{A}{10} x^{p-q} f'$$

$$= \left(\frac{9\nu J}{2\rho} \cdot \frac{J}{48\nu^2\rho} \right)^{1/3} x^{\frac{1}{2} - \frac{2}{3}} \operatorname{sech}^2 \left[\left(\frac{J}{48\rho\nu^2} \right)^{1/3} x^{2/3} \right]$$

$$= \left(\frac{3J^2}{32\rho^2\nu} \right)^{1/3} x^{-1/3} \operatorname{sech}^2 \left[\left(\frac{J}{48\rho\nu^2} \right)^{1/3} x^{2/3} \right]$$

$$u_{max} = \left(\frac{3J^2}{32\rho^2\nu} \right)^{1/3} x^{-1/3}$$

$$u = u_{max} \operatorname{sech}^2 \left[\left(\frac{J}{48\rho\nu^2} \right)^{1/3} x^{2/3} \right]$$

$$\frac{u}{u_{max}} = 0.01$$

$$\operatorname{sech}^2 \left[\left(\frac{J}{48\rho\nu^2} \right)^{1/3} x^{2/3} \right] = 0.01 = \operatorname{sech}^2 3$$

$$y|_{x=0} = \left(\frac{J}{48\rho\nu^2} \right)^{1/3} x^{2/3} = 3$$

So, now we have the solution f prime is equal to tan hyperbolic eta now, we can write the corresponding velocity profiles corresponding velocity profiles are u ok by u max ok u by u max is f prime and f prime you have seen that it is 1 minus f square and 1 minus f square. So, f is already we have written in terms of eta. So, 1 minus tan hyperbolic square eta; that means, sec hyperbolic square eta.

So, you can see that this will give the this velocity u which is function of x and y. Now velocity u already we have written as A by B x to the power p minus q f prime and p q A B value already we have assumed. So, you can write 9 nu J divided by twice rho and nu as 48 nu square rho by J. So, you can write this and to the power 1 by 3 x to the power 1 by

$3 \text{ minus } 2 \text{ by } 3$ and we have sec hyperbolic square y by $48 \text{ rho nu square divided by } J$ to the power $1 \text{ by } 3 \text{ x to the power } 2 \text{ by } 3$.

So, this is the eta, eta we have written as $y \text{ by } B \text{ x to the power } q$ ok. So, if you simplify it. So, you will get $3 \text{ j square divided by } 32 \text{ rho square nu to the power } 1 \text{ by } 3 \text{ x to the power minus } 1 \text{ by } 3$ sec hyperbolic square $y \text{ J divided by } 48 \text{ rho nu square to the power } 1 \text{ by } 3 \text{ x to the power minus } 2 \text{ by } 3$.

So, if we represent this as $u \text{ max}$. So, we can write $u \text{ max}$ is equal to $3 \text{ J square by } 32 \text{ rho square nu to the power } 1 \text{ by } 3 \text{ x to the power minus } 1 \text{ by } 3$. So, you can see that $u \text{ max}$ if you represent like this. So, you can write u is equal to $u \text{ max sec hyperbolic square } y \text{ J by } 48 \text{ rho nu square to the power } 1 \text{ by } 3 \text{ x to the power minus } 2 \text{ by } 3$ ok.

So, you can see this is nothing but sec hyperbolic eta square and this from this equation you can see that u is equal to $u \text{ max sec hyperbolic square eta}$ and that we have written and $u \text{ max}$ expression is this. So, now, let us find the width of the jet. So, we will represent the thickness of this width as the velocity near to the jet boundary it becomes one percent of the center line velocity $u \text{ max}$.

So, if you define in that way, then you can see from here your $u \text{ max}$ ok $u \text{ max}$ you can see it will decay right with $x \text{ to the power minus } 1 \text{ by } 3$ right. So, the maximum velocity decays like $x \text{ to the power minus } 1 \text{ by } 3$. So, from here you can see that $u \text{ by } u \text{ max}$ will become 1 percent right. So, it will be 0.01 ok. So, from here we can write sec hyperbolic square $y \text{ J by } 48 \text{ rho nu square to the power } 1 \text{ by } 3 \text{ x to the power minus } 2 \text{ by } 3$.

So, this will become 0.01 and this is sec hyperbolic square 3. So, from here you can see that y location. So, we are considering this is the center line. So, this is the jet boundary. So, in one way we are finding this y .

So, both way it will be just multiplied by 2 ok. So, when we are finding the thickness of the jet. So, you can see from here you can write y where u is becoming 1 percent of the $u \text{ max}$, $J \text{ divided by } 48 \text{ rho nu square to the power } 1 \text{ by } 3 \text{ x to the power minus } 2 \text{ by } 3$ is equal to 3 ok.

Two-dimensional Laminar Jet

Jet width,
$$2y_{1\%} = 2 \times 3 \left(\frac{48 \rho u^2}{J} \right)^{1/3} x^{2/3}$$
$$= 12 \left(\frac{6 \rho u^2 x^2}{J} \right)^{1/3}$$
$$\text{width} \approx 12 \left(\frac{6 \rho u^2 x^2}{J} \right)^{1/3}$$

Thus, the jet spreads as $x^{2/3}$.

So, from here you can find the jet width as $2y$ where u is becoming 1 percent of the u max as $2 \times 3 \times 48 \rho u^2$ divided by J to the power $1/3$ x to the power $2/3$ ok. So, this will become $12 \rho u^2 x^2$ by J to the power $1/3$ ok. So, we can see the width will be $12 \times 6 \rho u^2 x^2$ by J to the power $1/3$.

So, you can see that this width with x it will spread as x to the power $2/3$. So, thus the jet spreads as x to the power $2/3$. So, now, we are interested to find the volume flow rate at any location x ok. So, that just we need to integrate this velocity from y minus infinity to infinity.

Two-dimensional Laminar Jet

Volume flow rates

$$Q = \int_{-\infty}^{+\infty} u \, dy$$

$$= u_{\max} \int_{-\infty}^{+\infty} \operatorname{sech}^2(ky) \, dy$$

$$= 2u_{\max} \int_0^{\infty} \operatorname{sech}^2(ky) \, dy$$

$$= \frac{2u_{\max}}{k} \int_0^{\infty} \frac{d}{dz} (\tanh z) \, dz$$

$$= \frac{2u_{\max}}{k} [\tanh z]_0^{\infty}$$

$$= \frac{2u_{\max}}{k} \cdot 1$$

$$= \frac{2u_{\max}}{k}$$

$$u = u_{\max} \operatorname{sech}^2(ky)$$

$$k = \left(\frac{j}{48\rho\nu^2} \right)^{1/3} \frac{-2/3}{\alpha}$$

$$z = ky$$

$$dz = k \, dy$$

$$\frac{d}{dz} (\tanh z) = \operatorname{sech}^2 z$$

$$\tanh \infty = 1$$

$$\tanh 0 = 0$$

So, we can find the volume flow rate Q per unit width we are considering, because we are considering two dimensional case, so, per unit width -if you consider them Q will become integral minus infinity to plus infinity $u \, dy$ and u we have written as u_{\max} integral minus infinity to plus infinity $\operatorname{sech}^2(ky) \, dy$ where we know that u is equal to $u_{\max} \operatorname{sech}^2(ky)$ where k is equal to $\left(\frac{j}{48\rho\nu^2} \right)^{1/3} \frac{-2/3}{\alpha}$.

So, this we can write as $2u_{\max} \int_0^{\infty} \operatorname{sech}^2(ky) \, dy$. Now we can write z is equal to ky . So, dz will become $k \, dy$. So, and we can write d of dz of $\tanh z$ is $\operatorname{sech}^2 z$. So, this is nothing but $\operatorname{sech}^2 z$. So, this now we can write as $\frac{2u_{\max}}{k} \int_0^{\infty} \frac{d}{dz} (\tanh z) \, dz$.

So, this dz is equal to $k \, dy$. So, we have divided k here and we can write $\frac{2u_{\max}}{k} \int_0^{\infty} \frac{d}{dz} (\tanh z) \, dz$. So, you can see $\frac{2u_{\max}}{k}$. So, \tanh hyperbolic infinity is 1 and \tanh hyperbolic 0 is 0. So, from here you can see that it will become 1. So, we can write as $\frac{2u_{\max}}{k}$.

Two-dimensional Laminar Jet

$$Q_3 = 2 \left(\frac{3J^2}{32\rho^2\nu} \frac{48\rho\nu^2}{J} \right)^{1/3} x^{-1/3} x^{2/3}$$
$$Q_3 = \left(\frac{36J^2}{\rho} \right)^{1/3} x^{1/3}$$

Q_3 grows like $x^{1/3}$.

So, now if you put the value of k and u_{max} we can write the volume flow rate as $2 \frac{3J}{\rho}$ square divided by $32 \rho^2 \nu$ $48 \rho \nu^2$ by J to the power $1/3$ x to the power $-1/3$ and x to the power $2/3$. So, you can write Q as $36 \frac{J^2}{\rho}$ divided by ρ to the power $1/3$ x to the power $1/3$.

So, from this expression you can see that volume flow rate increases in the axial direction x with x to the power $1/3$ so; that means, Q grows like x to the power $1/3$. So, in today's lecture we considered laminar two dimensional jet where in z direction there is no variation of velocity and any gradient of any property is 0. So, x is the axial direction and at x equal to 0 we have a high velocity from the slit of height h .

So, this uniform velocity is considered as u_{naught} and when it will pass through this jet obviously, due to momentum diffusion this jet width will increase in the axial direction, but we have shown one important property here that the momentum flux ok becomes constant along x ok .

So, from using that property we have found the velocity distribution of the jet where u becomes almost 1 percent of the center line velocity u_{max} and then finally, we have calculated the volume product per unit width.

Thank you.
