Lecture - 32
Incompressible Viscous Flows Part-IV

Good afternoon, welcome you all to this session fluid mechanics we are discussing about the different types of parallel flows. Now today, we will be discussing another type known as Hagen Poiseuille flow.

(Refer Slide Time: 00:33)

Let us concentrate here Hagen, so now we will discuss Hagen Poiseuille flow; we have discussed the plane Poiseuille flow in the last class; names of the two people, who developed the equations for this flow, after they are named this Hagen Poiseuille flow. This is basically flow through a circular tube, so if we consider like this is a circular tube like this or rather yes. So, this is Hagen Poiseuille flow the flow through a, I am sorry. So, you can just change this, so this is not good. So, we can change it, we can make it again Hagen Poiseuille flow. I am sorry we can make it again Hagen Poiseuille flow, this is, this designates the flow through a tube, circular tube let this is the flow through a tube of circular cross section. So, this is the flow, so this is the axis.

So, here similarly if we first we fix the coordinate axis for all types of fluid, we fix the cylindrical polar coordinate; that means, z from here you measure z, any point we

measure at r and azimuthal location. That means, if this with the r this location with the r here this is the surface not here, so this is the azimuthal location. That means, r θ z at the coordinate, r is the radial coordinate at the surface, it is R ; that means, this one is R , R , the radius of this circle. Any point has got a radial coordinate r from the axis, this is the z in this direction and θ is the azimuthal direction. So, these three coordinates as you know; defines the cylindrical polar coordinates, compatible with the geometric flow, through a cylinder tube of circular cross section.

Now, again if we consider a parallel flow, parallel flow fully developed incompressible laminar flow; which is already told fully developed, I also write. The meaning of this is not totally appreciated at this moment, fully developed laminar study all these things are there, study incompressible flow, incompressible flow, All right. Now, when it is a parallel flow definition wise here, we define V_z naught is equal to 0. The flow is always in the axial direction, there is no component of velocity in the radial or in the azimuthal; that means, tangential direction; that means, V_r is 0 V_r and V_θ all 0.

So, as per as our routine application, if we write the incompressible flow continuity equation in cylindrical coordinate system if you recall $\frac{\partial V_r}{\partial r} + V_r \frac{1}{r} + \frac{\partial V_\theta}{\partial \theta} + \frac{\partial V_z}{\partial z} = 0$, V_r V_θ V_z at the V_z z direction velocity, V_r is r direction velocity and V_θ is θ direction velocity, tangential velocity azimuthal direction, but incidentally they are 0 for parallel flow.

So, continuity equation that is divergence of the velocity vector in cylindrical coordinates stands like that, as I told you earlier while discussing continuity equation. Now $V_r = 0$ $V_\theta = 0$ only one component of velocity exist and as is consequence is well consequence; that means, V_z is not a function of z because, $\frac{\partial V_z}{\partial z} = 0$ another thing we have to consider here that the flow is symmetrical about these axis symmetrical flow about the axis r is equal to 0 which means that the flow is azimuthally, azimuthally symmetrical. That means, $\frac{\partial}{\partial \theta}$; that means, there is no variation of any parameter with respect to θ all parameters are functions of r and z we consider. That means, with θ there is no variation $\frac{\partial}{\partial \theta}$ of any parameter is 0 which means, that any r z plane at any θ is represents the similar flow situations. That means, it is symmetrical therefore, V_z cannot be according to this definition, cannot be function of θ the flow is symmetrical about the axis.

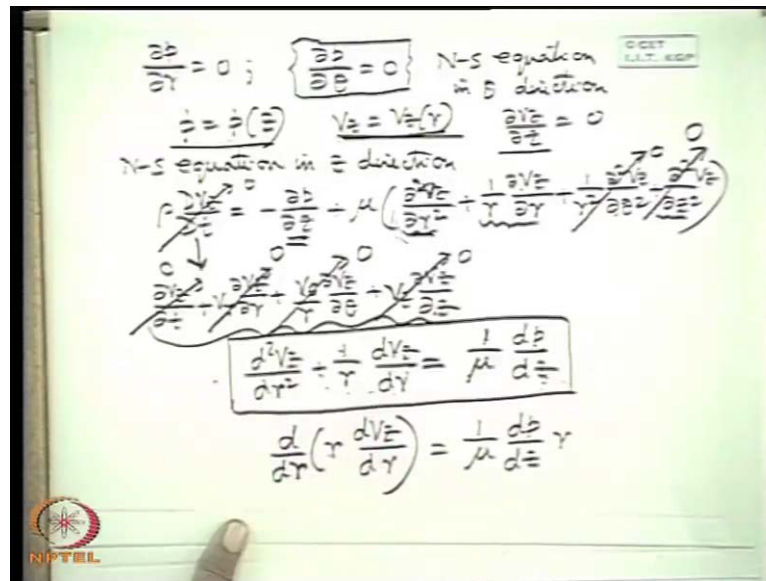

So, therefore, only go is that V_z is a function of r ; that means, V_z is a function of the perpendicular coordinates, coordinates in the perpendicular direction to the velocity. This is the usual consequences; which we found in case of Cartesian coordinate system, we use a function of y where, V is the velocity component in x direction and only existent velocity component. So, here also like that V_r, V_θ, V_z is a function of r .

Now, I write Navier-Stokes equations, Navier-Stokes equations. That is equation of motions, in art directions. So, what is the equation $\rho D V_r / D t$ that is, the acceleration minus V_θ^2 / r in art direction is equal to minus $\partial p / \partial r$. If you write this equation you have to just make practice, that now for incompressible flow, so, only these Laplacian term will be there and that in cylindrical coordinate takes this form, $\nabla^2 V_r$ has to develop this habit to write the Laplacian $\nabla^2 V_r = \partial^2 V_r / \partial r^2 + 1/r \partial V_r / \partial r + \partial^2 V_r / \partial z^2 - V_r / r^2$ due to the curvature this two terms comes $2/r \partial V_\theta / \partial \theta$. So these are the terms for the Laplacian and for incompressible flow, this is the art direction Navier-Stokes equation, the equation of motion in art direction.

Let us see what does it give, $D V_r / D t = 0$ there is no V_r even, if we split it if one wants to see $\partial V_r / \partial t$ the temporal term plus $V_r \partial V_r / \partial r$ convective term plus that you as you know $V_\theta / r \partial V_r / \partial \theta$ well, plus $V_z \partial V_r / \partial z$. So, each and every term is 0, temporal derivative is 0. So, $V_r \partial V_r / \partial r = 0$, more over $V_\theta / r = 0$. Though V_z is not 0, but $\partial V_r / \partial z = 0$ there is no V_r .

So, therefore, as a whole this substantial derivative is 0 there is no $V_\theta = 0$ all these terms are 0 because, V_r is non existence. So, there is no V_r and its gradient V_θ / r , so, therefore, the only consequence is that $\partial p / \partial r = 0$.

(Refer Slide Time: 07:52)

So, therefore, we get $\frac{\partial p}{\partial r}$ again we get from azimuthal symmetry $\frac{\partial p}{\partial \theta}$ is 0, but this $\frac{\partial p}{\partial \theta} = 0$, we can obtain also from Navier-Stokes equations in the θ direction. But it is not required now because, unnecessarily we may not write this equation to get $\frac{\partial p}{\partial \theta} = 0$ because, we have considered then azimuthally symmetric flow that is, flow is symmetrical about the z axis, $\frac{\partial}{\partial \theta}$ of any parameter is 0; that means, $\frac{\partial p}{\partial \theta}$ is 0.

So, only go is this, p is a function of z , its complete, so, V_z is a function of r and p is a function of r this you keep in mind. Now write the z-direction Navier-Stokes equation, N-S equation in z direction, N-S equation in z ; that means, along the axis of the z direction. Write $\rho \frac{dV_z}{dt}$ so, $\frac{dV_z}{dt}$ is the only acceleration in z direction unlike r and θ direction no cross component come. So, this must be equal to $-\frac{\partial p}{\partial z}$ plus μ Laplacian of V_z ; that means, $\nabla^2 V_z$ in cylindrical polar coordinate you know the operator is like that, $\frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{1}{r^2} \frac{\partial^2}{\partial \theta^2} + \frac{\partial^2}{\partial z^2}$ operating on V_z , plus $\frac{\partial^2}{\partial z^2}$ operating on V_z . So, this is the Laplacian.

Now, let us see this is 0, why? If you just now it difficult to accept this is 0, why? Because V_z is not 0 why $\frac{dV_z}{dt} = 0$ let us split it, then only you will accept plus so, this becomes $V_r \frac{\partial V_z}{\partial r}$ the convective part plus $V_\theta \frac{\partial V_z}{\partial \theta}$ plus

$\frac{\partial V_z}{\partial z}$ All right. Now it is clear that each and every term is 0 for steady flow, this is $\frac{\partial V_z}{\partial t}$ now $\frac{\partial V_r}{\partial r}$ is non-existent. So, this term is 0 $\frac{\partial V_\theta}{\partial \theta}$ is 0 and more over $\frac{\partial \theta}{\partial \theta}$ of any parameter is 0, it is 0. Now though V_z is non 0, but $\frac{\partial V_z}{\partial z}$ is 0 from continuity. So, that we write V_z is a function of r because, continuity has already told us $\frac{\partial V_z}{\partial z} = 0$ for these, this is 0.

So, therefore, we see all the terms as 0, so, $\frac{D V_z}{D t} = 0$. Here you see this is not 0, now where we find that this is 0, this is also not 0, but this is 0 because, no parameter is a function of θ . So, second derivative of θ is also 0. Now this can be neglected with respect to $\frac{\partial^2 V_z}{\partial r^2}$, why? Now $\frac{\partial V_z}{\partial z}$ may be 0, but $\frac{\partial^2 V_z}{\partial z^2}$ may not be 0, but if we consider $\frac{\partial V_z}{\partial z} = 0$ $\frac{\partial^2 V_z}{\partial z^2}$ may be 0, but we can argue in a different way that the length of the tube is much more compared to the radius. So, that variation in z direction is neglected compared to that in the r . Mathematically also one can tell if, $\frac{\partial V_z}{\partial z} = 0$, $\frac{\partial^2 V_z}{\partial z^2}$ is also 0. So, both ways we can tell this is 0.

So, therefore, we can we are having with this these and these, but it has been proved that p is a function of z only. So, we get rid of $\frac{\partial}{\partial z}$, so, we write only ordinary differential similarly, it has been proved that V_z is a function of r only. So, therefore, this is also 0, so, therefore, $\frac{\partial V_z}{\partial z}$, we get rid of $\frac{\partial}{\partial z}$. So, therefore, I write this first that $\frac{d^2 V_z}{d r^2} + \frac{1}{r} \frac{d V_z}{d r} = \frac{1}{\mu} \frac{d p}{d z}$. It is a similar equation that we arrived in Cartesian coordinate there we arrived $\frac{d^2 u}{d y^2} = \frac{1}{\mu} \frac{d p}{d x}$, here x coordinate is the z direction. That means z is the direction of flow r is this direction the radial direction, the governing equation is $\frac{d^2 V_z}{d r^2} + \frac{1}{r} \frac{d V_z}{d r} = \frac{1}{\mu} \frac{d p}{d z}$. V_z is a function of r that is why it is an ordinary differential equation and p is a function of z . With this same argument we can tell that if $\frac{d p}{d z}$ is constant and left hand side is constant; that means, if V_z is a function of r only. So, $\frac{d^2 V_z}{d r^2} + \frac{1}{r} \frac{d V_z}{d r}$ can either be constant or a function of r , $\frac{1}{\mu} \frac{d p}{d z}$ is either a function of r or constant. That means, as a whole left hand side option is there either a function of r or constant, and since p is a function of z the option for right hand side is either is a function of z or constant, depending upon either p is a linear function of z or non-linear function of z . But a function of r cannot be made equal to a function of z . So, therefore, the equality between the LHS and RHS the left hand side and right hand side tells that this is constant and this is they can only match at a constant value which means that V_z

is a quadratic function of r . So, that this gives constant value independent of r and p is a linear function of z . So, that this gives a constant value; that means, $\frac{dp}{dz}$ is constant.

Now, you just integrate it how to integrate you write in this fashion by multiplying r this is a simple calculus differential equation. So, there is nothing fluid mechanics any if you just multiple r . So, you get $r \frac{d}{dr} (r \frac{dv_z}{dr}) + \frac{d}{dz} (r^2 \frac{dv_z}{dz}) = 0$ which can be written as $\frac{d}{dr} (r^2 \frac{dv_z}{dr}) + \frac{d}{dz} (r^2 \frac{dv_z}{dz}) = 0$; that means, if you multiple r on both the sides I get this multiply at $r \frac{d}{dr} (r^2 \frac{dv_z}{dr}) + \frac{d}{dz} (r^2 \frac{dv_z}{dz}) = 0$; that means, $r^2 \frac{d}{dr} (r^2 \frac{dv_z}{dr}) + \frac{d}{dz} (r^2 \frac{dv_z}{dz}) = 0$; that means, I can write them by multiplying with r left hand side like this.

(Refer Slide Time: 14:23)

Navier-Stokes equation in z direction

$$\rho \frac{\partial v_z}{\partial t} = -\frac{\partial p}{\partial z} + \mu \left(\frac{\partial^2 v_z}{\partial r^2} + \frac{1}{r} \frac{\partial v_z}{\partial r} - \frac{1}{r^2} \frac{\partial^2 v_z}{\partial \theta^2} + \frac{\partial^2 v_z}{\partial z^2} \right)$$

$$\frac{d^2 v_z}{dr^2} + \frac{1}{r} \frac{dv_z}{dr} = \frac{1}{\mu} \frac{dp}{dz}$$

$$\frac{d}{dr} \left(r \frac{dv_z}{dr} \right) = \frac{1}{\mu} \frac{dp}{dz} r$$

$$r \frac{dv_z}{dr} = \frac{1}{2\mu} \frac{dp}{dz} r^2 = C_1$$

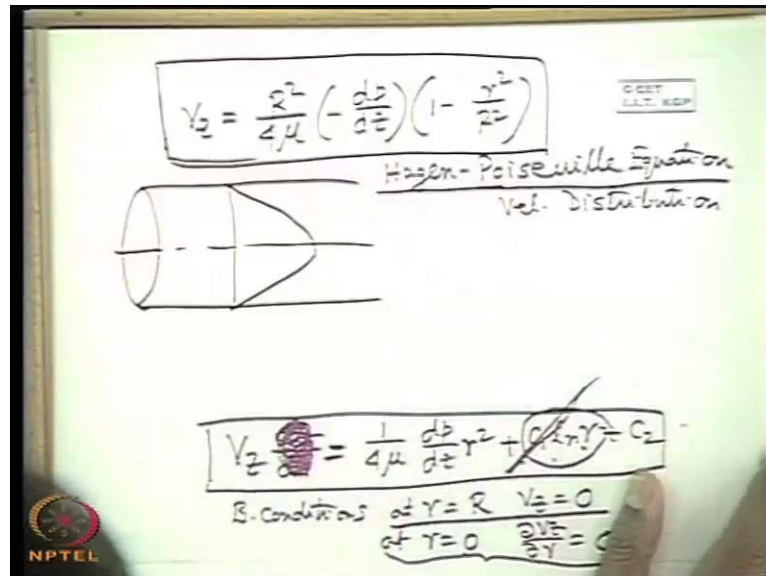

$$v_z = \frac{1}{4\mu} \frac{dp}{dz} r^2 + C_1 \ln r + C_2$$

Then what I can do I can integrate this. So, if you integrate this first line will be $r \frac{d}{dr} (r \frac{dv_z}{dr})$ r is equal to $\frac{1}{2\mu} \frac{dp}{dz} r^2$ very simple plus C_1 . So, second integration give $\frac{d}{dr} (r \frac{dv_z}{dr})$ now this will be C_1 by r and this will be again r ; that means, $\frac{1}{4\mu} \frac{dp}{dz} r^2$ into again r square because, this will be divided. So, r^2 by r ; that means, $r \frac{d}{dr} (r \frac{dv_z}{dr})$ again r square by $2 \times 4\mu$ plus C_1 by r will give you $C_1 \ln r$, C_1 by $r \frac{d}{dr} (r \frac{dv_z}{dr})$ second integration C_1 another integration constant C_2 .

So, therefore, I am also playing like $(\frac{1}{4\mu}) \frac{dp}{dz}$, then integration gives v_z is $\frac{1}{4\mu} \frac{dp}{dz} r^2$ plus $C_1 \ln r$ plus C_2 very good. So, this is the differential equation. Now you tell me what are the boundary conditions to find out C_1 C_2 , you must have a look to this that, this is the picture what are the boundary conditions you tell me,

tell me the boundary conditions; that means, if I keep it like this what are the boundary conditions this is the flow.

(Refer Slide Time: 15:34)

So, what are the boundary conditions, so, boundary conditions, boundary conditions at r is equal to R what V_z is equal to 0 , but one boundary condition then what to do about c_1 c_2 at r is equal to 0 very good tell me at r is equal to 0 $\frac{dV_z}{dr}$ is 0 . Because, this is symmetry about this symmetrical about this axis, but this is not required vigorously, mathematically, one can simply argue that at r is equal to 0 , the flow field is defined. So, this term cannot exist because, this term cannot define the equation physically that r is equal to 0 , it is undefined; with an $\ln r$ terms. So, c_1 is 0 or if you tell that r is equal to 0 both way we can tell this is physically, we can eliminate this term or we can eliminate this term mathematically also by telling that since it is symmetric about r is equal to 0 . So, $\frac{dV_z}{dr}$; that means, the derivative has to be 0 with a maximum or minimum at r is equal to 0 and mathematically if we look that, $\frac{dV_z}{dr}$ just the previous step, before integration is this. So, at r is equal to 0 $\frac{dV_z}{dr} = 0$ means $c_1 = 0$.

So, either way we can tell $c_1 = 0$. So, from this equation precisely we get c_2 and finally, what we get is V_z is equal to after having this R^2 by 4μ because, this is the value of $c_2 \frac{dp}{dz}$. So, minus $\frac{dp}{dz} \frac{r^2}{4\mu}$ I always write like this, into $1 - \frac{r^2}{R^2}$ by R^2 . This is precisely the velocity distribution equations and this is a parabola; that means, if you draw it again I am drawing this; that means, if you draw it. So, it is a again

sort of parabola, it has to be a parabola we have seen the quadratic equation, this is known as Hagen Poiseuille equation or simply Poiseuille equation if the what plane they are adjective Hagen Poiseuille equation.

Plane Poiseuille equation is the equation velocity distribution between two fixed plate. So, either Hagen Poiseuille or Poiseuille equation, this is the velocity Poiseuille equation or Poiseuille velocity distribution or Hagen Poiseuille velocity distribution. The word Hagen Poiseuille or only Poiseuille without any adjective means, that it is the equation for a parallel flow through a pipe or through a duct of circular cross section through a cylinder.

(Refer Slide Time: 18:28)

The image shows a whiteboard with handwritten mathematical derivations for the Hagen-Poiseuille flow. At the top, the velocity profile is given as $V_z = \frac{R^2}{4\mu} \left(-\frac{dp}{dz}\right) \left(1 - \frac{r^2}{R^2}\right)$. Below this, the maximum velocity is $V_{z,max} = \frac{R^2}{4\mu} \left(-\frac{dp}{dz}\right)$. To the right, a diagram of a pipe of radius R shows a differential annular element of thickness dr at radius r . The flow rate Q is equated to the integral of the velocity profile over the cross-section: $Q = \int_0^R V_z(r) \cdot 2\pi r dr$. The final result for the average velocity is $V_{z,av} = \frac{Q}{A} = \frac{2}{R^2} \int_0^R V_z(r) r dr$. A small box in the top right corner of the whiteboard reads "GCEET U.T. KGP". An NPTEL logo is visible in the bottom left corner.

So, the velocity distribution is this $V_z = \frac{R^2}{4\mu} \left(-\frac{dp}{dz}\right) \left(1 - \frac{r^2}{R^2}\right)$, so again I write $V_z = \frac{R^2}{4\mu} \left(-\frac{dp}{dz}\right) \left(1 - \frac{r^2}{R^2}\right)$; where is V_z maximum at r is equal to 0. So, maximum V_z is $\frac{R^2}{4\mu} \left(-\frac{dp}{dz}\right)$, another thing is clear that, the sign of V_z represented by sign of $\frac{dp}{dz}$ when $\frac{dp}{dz}$ is 0 V_z is 0; that means, flow is entirely governed by the pressure gradient. A negative pressure gradient causes a velocity in the positive z directions and vice versa; obviously, it has to be that this is the z direction a positive V_z means the negative pressure gradient. That means, pressure here is higher, pressure here is lower and the opposite is also true and if $\frac{dp}{dz} = 0$ V_z is 0.

Now, question comes how to find out average velocity; that means, first of all we will have to find out Q because, we know average flow velocity is Q by area, what is the definition of average velocity V_z average is Q by area. So, what is Q ? How to define Q ? So, to define Q , what we have to do, we have to consider an elemental ring at a distance r , at a distance r and elemental ring you understand? Of thickness the thickness dr here better if I write like if, I draw like this. You consider an elemental ring this is the circular cross section here at any radius r , that at any radius r you consider an elemental ring of thickness dr . This is the radius r we consider an elemental ring thickness here dr , and find out what is the flow rate through this annulus. Flow rate through this annulus is, flow rate through this annulus is the u or V_z here V_z at that r which is a function of r given by this, into what is the area of this annular ring $2\pi r dr$. So, simply integrate it 0 to r , this is capital R that is the radius.

So, therefore, if I write π so, V_z is this sorry Q is this. So, what is V_z average? So, V_z average is I like to show you what I told you last class that V_z average is Q by A ; that means, 0 to r now 2π I can take. So, V_z as a function of r into $r dr$ divided by πr^2 . So, is equal to 2 by R^2 0 to r $V_z r dr$. So, you see it is not a simple arithmetic mean it is an weighted average V_z into $r dr$ not $V_z dr$ by into 2 by r . This could have been the arithmetic average in this case, it is not an arithmetic average another typical V_z average 2 by r^2 $V_z r dr$. So, how do you know that this type of average will be there, this depends upon the geometry because, we know the basic definition of V_z average is Q by A . So, simply we define Q and then divided by area, we can define the expression for the average velocity. Here it is not like that $u dy$ divided by 1 by h , so, it is not $V_z dr$ divided by 1 by r either it is $V_z r dr$ 2 by R^2 ; that means, it is a typical average y z average V_z into $r dr$ which has come from the definition of the flow rate. I am sorry, I am sorry this is R ; this has to be R^2 very good.

(Refer Slide Time: 22:34)

$$Q = \frac{\pi R^4}{8\mu} \left(-\frac{dp}{dz}\right)$$

$$V_z = \frac{R^2}{4\mu} \left(-\frac{dp}{dz}\right) \left(1 - \frac{r^2}{R^2}\right)$$

$$Q = 2\pi \int_0^R V_z(r) \cdot r \, dr$$

$$V_{z,av} = \frac{Q}{\pi R^2} = \frac{R^2}{8\mu} \left(-\frac{dp}{dz}\right) = \frac{V_{z,max}}{2}$$

Now we find out the value of Q, if you substitute this V_z there is a function of r ; that means, this function if we substitute with 2π at here 2π , you take out and you find out the integration draw do the integration, you will find that Q becomes equal to R^4 by 8μ into minus dp/dz into πR^4 rather I write πR^4 this is the value of Q. If you solve this integration; that means, it comes Q is equal to twice π integration of 0 to r V_z as a function of r into $r \, dr$; that means, that function of r you substitute.

What is that V_z is equal to R^2 which we have got as Hagen Poiseuille velocity distribution minus dp/dz into $1 - r^2$ by R ; that means, if you substitute this integrate you get this. So, therefore, V_z average as Q by πR^2 that is the cross sectional area is simply, πR^2 by 8μ minus dp/dz the relationship with the V_z maximum is $V_{z,max}$ by 2 maximum is πR^2 by 4μ . If you recall the maximum velocity, the maximum velocity we got as, πR^2 by 4μ $V_{z,max}$ maximum is R^2 by 4μ minus dp/dz . So, π is equal to R^2 by 8μ dp/dz , V_z maximum is R^2 by 4μ minus dp/dz .

(Refer Slide Time: 24:19)

The whiteboard contains the following derivations:

$$V_z = \frac{R^2}{8\mu} \left(-\frac{dp}{dz}\right)$$

$$\tau_{wall} = \tau_{at r=R} = -\mu \left(\frac{dV_z}{dr}\right)_{at r=R}$$

$$V_z = \frac{R^2}{4\mu} \left(-\frac{dp}{dz}\right) \left(1 - \frac{r^2}{R^2}\right)$$

$$\frac{dV_z}{dr} = \frac{R^2}{4\mu} \left(\frac{dp}{dz}\right) \frac{2r}{R^2} = \frac{R}{2\mu} \left(\frac{dp}{dz}\right)$$

$$\tau_w = \frac{R}{2} \left(-\frac{dp}{dz}\right) = \frac{R}{2} \frac{8\mu V_{z,avg}}{R^2}$$

$$\tau_w = \frac{4\mu V_{z,avg}}{R}$$

V_z average R square by 8μ minus dp/dz . τ_w we are interested now τ_w wall shear stress at the wall; that means, is equal to τ at r is equal to R it is minus $\mu dV_z/dr$, dV_z/dr is the velocity gradient and that is equal to the shear rate. Why minus sign I am writing here, can you tell? Why minus dV_z/dr at r is equal to R ; this is because, here the coordinate axis has been chosen in such a way that, the r is measured from this axis and the velocity, if you see here the velocity. I think it will be a better figure here if you see here, that the velocity profile is such that the velocity is decreasing with the increasing r . That means, r is not measured from the solid surface, solid surface always velocity is 0 when the solid surface is at the rest, that is the no slip condition. So, velocity must increase from the solid surface and always the normal coordinate should be measured from the solid surface, we will see afterwards we define some wall coordinate or normal coordinate from the wall; which is perpendicular to the wall along outwardly, but here in this conventional cylindrical coordinate the r is measured from the centre. So, an increasing r shows a decreasing velocity to make account for this, we make conventionally a minus sign in defining τ_w .

So, now rest part is the simple mathematics. So, dV_z/dr what is V_z better I write V_z also. So, all at a time space is so small here 4μ minus dp/dz into $1 - r^2/R^2$. So, what is dV_z/dr ? dV_z/dr is now it is twice r and R is equal to r means it is twice R , R^2 let us write. So, R^2 4μ minus minus cancels dp/dz into $2R$ R^2 and $2R$ means at R is equal to $2R$; that means, R^2/R^2 cancels.

So, it is R by 2 into d p d z . So, therefore, R by 2 I am sorry 2μ , so, therefore, τ_w is minus μ , so, $\mu \mu$ will cancel; so R by 2 minus d p d z . So, this is the value of wall shear stress are there we should make it in terms of the V_z average; that means, R by 2 into $8 \mu V_z$ average understand 8μ average V_z average by R square; that means, I just substitute d p d z in terms of the V_z average. That means τ_w becomes is equal to $4 R \mu V_z$ average by, I am sorry $4 \mu V_z$ average by this cancels R . So, this is the expression of τ_w in terms of V_z average; that means, minus d p d z is V_z average 8μ by R square. So, this is V_z average 8μ by R square, so, V_z average is 8μ by R square. So, R R cancels, so, $4 \mu V_z$ average by R .

(Refer Slide Time: 28:15)

The whiteboard shows the following derivations:

$$C_f = \frac{\tau_w}{\frac{1}{2} \rho V_{z,avg}^2} = \frac{16}{(PV_{z,avg}(2R)/\mu)} = \frac{16}{Re}$$

$$\frac{PV_{z,avg} D}{\mu} = Re \quad (\text{for flow of fluid through a cylindrical duct})$$

$$D_h = \frac{4A}{p} = \frac{4 \frac{\pi D^2}{4}}{\pi D} = D$$

A boxed equation at the bottom right states: $C_f = \frac{16}{Re}$

Now, what is the next step? Next step is skin friction coefficient C_f . So, C_f is defined as τ_w by half ρV_z average square, if you do that, you get an expression you can see it 16 by ρV_z average into $2 R$ actually it is 8 I just multiplied divided by μ . So, this ρV_z average $2 R$ is diameter of the D by μ is equal to Reynolds number for flow, flow of fluid through circular duct, through a cylindrical duct, circular cross section, through a cylindrical duct.

The Reynolds number is defined ρ the characteristic velocity is V_z average, that is flow rate by cross sectional area times the diameter of the tube; which is the hydraulic diameter, $D_h = \frac{4A}{p}$ cross sectional area by weighted perimeter $4 \pi D$ square by 4 divided by 5 . So, it is simply D , so this is the definition of Reynolds number we will

come again. So, therefore, C_f is 16 by Reynolds number; which is very important that in a pipe flow that Hagen Poiseuille flow, C_f is 16 by Reynolds number. It is inversely proportional, in case of plane Poiseuille flow it was 12 by Reynolds number, C_f is 16 by Reynolds number. So, Reynolds number definition is, $\rho V z \text{ average } D$ by μ . So, this is about the Hagen Poiseuille flow, all aspects of Hagen Poiseuille flow. So, any queries?

So, today well I will leave here and thing is that, next class we will start a new chapter that is, the viscous flow through pipes the application of viscous flow. So, about the exact solutions I just like to make a brief closer before ending this section that, today we started this class we started with the derivation of viscous momentum equation or equation of motions for a viscous flow; and we first recognized that for a fluid at rest the only stresses at the pressure. The normal stresses, which or compressive in nature and same from all direction the viscous flow. For an ideal fluid flow we have considered that, if we take a fluid element the only surface forces at the normal forces which or thermodynamic pressure or static pressures, but for a frictional fluid or viscous fluid along with the normal forces, there are shear stresses. So, therefore, if we recognize the external forces apart from the body forces the surface forces consist of both the normal stresses and these shear stresses for a viscous fluid.

So, then we developed the equation of motion; that means, we equated the mass time acceleration with the external forces, we wrote the external forces in terms of the stress components. The most vital part is the relationship between stress and the strain at components, if we want to express the equation of motion in terms of the velocity components and the pressure; which we did not do in this class, but we recognize the different assumption based on which stress and strainless relationship is developed and finally, accepted that relationship. The assumptions well like that the fluids behave in such a way that, the relationship between stress and rate of strain are linear, and there is a class of fluids; which behaves so and known as Newtonian fluid, which stress and rate of strength behavior or relationship is linear. This has been found experimentally, and this relationship is invariant with coordinate transformation. Another assumption was that the fluids for which the equation of motions will be developed they are viscous fluids, but the second coefficient of viscous it is 0 . And another assumption last assumption was that the equation of motion will be derived in such a way the continuity to hydro static should be there. That means, you see the equations of motion; that is the Navier-Stokes

equation, if you put all $u, v, w = 0$ you get the equations of hydro static, if you put μ is equal to 0, you will get the Euler's equations. So, all continuity are there to known in viscid flow, friction less flow, and even for the hydro static cases; so, therefore, we will see that the continuity is there. So, based on this the stress and strain less relationships are developed and finally, this were substituted you got the equations of motions in terms of the velocity and pressure, and this equations are known as Navier-Stokes equation, named it after the two person Navier and Stoke.

Then we recognized the nature of the Navier-Stokes equation that, it is a practical differential equation definitely u, v, w being the dependent variables are functions of x, y, z and t . There are 4 independent parameters x, y, z and t , and there are four dependent variables u, v, w and pressure. We have 4 equations 3 equations of motion in three coordinate directions and one is the equation of quantity, so, they can be solved.

So, now the nature of the equation is they are practical differential equation, there order is 2, second order is governed by the viscous duct, Laplacian duct. Then the linear about the linearity and non-linearity; this is a non-linear equation because, if you see the acceleration part it is the convective acceleration which is non-linear in nature. $u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y}$, this gives a power of 2 for the dependent variable velocity component.

So, as a whole the Navier-Stokes equation is a non-linear second order of practical differential equation, which do not have a close form solutions, but there are certain cases simple cases of flow; where we have exact solutions close form solutions or Navier-Stokes equations. In those simplified cases by the physics of the problem, the basic Navier-Stokes equation; which is non-linear second order equations are been transformed to a very simple ordinary differential equations, even in second order, but linear ordinary differential equations. Those cases are parallel flows and we discussed the solutions of some parallel flows, again Poiseuille flow, plane Poiseuille flow, and quiet flow; that was the coverage of this section.

Thank you.
