Finite Volume Method for Fluid Flow Calculations: SIMPLE algorithm – Part III

(Refer Slide Time: 00:14)

6.4) $C|u|u + \frac{dp}{dx} = 0$

$\frac{d(UA)}{dx} = 0$

$x_2 - x_1 = x_3 - x_2 = 2$

Use SIMPLE algorithm and calculate p_2, U_B and U_C

Given: $C_B = 0.25$ $C_C = 0.2$ $A_B = 5$ $A_C = 4$

$p_1 = 200$ $p_3 = 38$

1D flow through a porous material

The diagram shows a horizontal pipe with three nodes labeled 1, 2, and 3. Node 1 is on the left, node 2 is in the middle, and node 3 is on the right. A dashed box encloses nodes 2 and 3. Arrows indicate flow from left to right. Node A is at the inlet, node B is at the interface between nodes 1 and 2, and node C is at the interface between nodes 2 and 3.

Hello everyone. Welcome to another lecture as part of our ME6151 Computational Heat and Fluid Flow course. So, in the last lecture, we looked at 3 problems from Patankar's book, right. From chapter 6, we looked at the 6.4, 6.5 and 6.7, these 3 problems we percolated them, kind of set the simple algorithm loop. So, in today's lecture we are going to see the corresponding programs for these problems and kind of run and obtain the answers, ok.

So, the first problem, we will tackle today is the problem number 6.4 that is the flow through a porous a 1-dimensional flow through a porous material. Essentially, this is governed by the equation $C|u|u + \frac{\partial P}{\partial x} = 0$, right. And we were given the pressure points which are 1, 2, 3 and the velocity points which are B and C, right.

And, the continuity equation was given as $\frac{d(uA)}{dx} = 0, \Delta x$ that is x_2 minus x_1 or x_3 minus x_2 was given as 2. And we were also given the constants the porosity coefficients, right, C_B, C_C as 0.25, 0.2.

(Refer Slide Time: 01:23)

The whiteboard contains the following text and diagram:

$$\frac{d(UA)}{dx} = 0$$

$$x_2 - x_1 = x_3 - x_2 = 2$$

Use SIMPLE algorithm and calculate p_2, u_B and u_C

Given: $C_B = 0.25$ $C_C = 0.2$ $A_B = 5$ $A_C = 4$

$p_1 = 200$ $p_3 = 38$

Initial guess: $u_B^* = u_C^* = 15$ $p_2^* = 120$

Discard the momentum equations: $c|u|u + \frac{dp}{dx} = 0$

The diagram shows a horizontal line with three points labeled 1, 2, and 3. Vertical dashed lines extend from points 1 and 2 down to a horizontal dashed line, forming a rectangular shape. A vertical dashed line also extends from point 3 down to the same horizontal dashed line.

And the cross sectional areas A_B, A_C are given as 5 and 4. And the pressure boundary condition is given at the points 1 and 3 that is 238, right. And we were given an initial guess that is $u_B^* = u_C^*$ equals 15 and P_2^* equals 120, right. And we have to find what is the converged value for the velocities u_B and u_C , and also the pressure 1, P_2 , right. That is what we have to find. So, the corresponding code the program with they have is in FORTRAN.

(Refer Slide Time: 02:04)

```
p2 = 120.0

All the programs that I have that I am going to show you today are in FORTRAN. So, I do not have the C counterparts of these, but if you want you can easily write them by looking at by looking at the code that this code that I will share with you. So, if you want you can write a C counterpart of it or you can even run use the FORTRAN programs to kind of play with them and see how they are written and how whether it will work for different values or not, and then kind of learn from it, ok.

So, essentially what we are looking at this code for simple porous that is problem 6.4. So, we have we kind of, so essentially this is the declaration part, so essentially we are declaring these variables that is the cross sectional areas A_B , A_C and the porosity c_B , c_C and the pressures P_1 , P_2 , P_3 ; Δx is basically your x_2 minus x_1 and so on and your tolerance and a_B , a_C here with little a these kind of correspond to the coefficients, right, in terms of the a_B is the coefficient for the u_B , right whenever we write.

And then u_B , u_C are the velocities at B and C locations. u'_B u'_C are the corrections for velocities for u_B , u_C , and P'_2 is the correction for pressure at the location 2. Then, we have the under relaxation that is α_u , α_p the coefficient.

And then we also have something known as residual which is both for u as well as for continuity, ok, for the u momentum equation and for the continuity equation. And then we have this b, b corresponds to the b term on your in your continuity equation, right, ok.

And then we have we kind of make use of couple of integers i and $imax$, ok. So, what is given to us? The initial guess was given as u_B equals 15, u_C equals 15 and pressure equals 120, right that is what was given, essentially u_B , u_C is equal to 15 and pressure equals 120. So, we initialize to that we have another set here which have we will try later, and anything in an exclamation series a comment, ok, so you do not have to worry about that.

deltax = 2.0

! set under-relaxation, tolerance
tolerance = 1.0e-6
alphaP = 0.8
alphaU = 0.9
imax = 200

do i = 1, imax

```

Then, the given parameters are the porosities c_B , c_C is 0.25 and 0.2, that is basically given here. And the cross sectional areas are 5 and 4, that is basically A_B is 5, A_C is 4 and pressures the Dirichlet boundary condition for pressure that is P_1 is 200 and P_3 is 38, ok. So, that is basically taken here. And the Δx is equal to 2 that is your x_2 minus x_1 or x_3 minus x_2 equals 2, ok. So, these are all the data that is already given in the problem. So, this data is given.

Next, what we do is we kind of set these values the tolerance values, so what is the smallest value we want to converge this code 2, that is 1 into 10 power minus 6. Then, the under relaxation values for the pressure we kind of set it as 0.8, for the velocity we set it set it as 0.9, ok.

Then, we would also need to do some iterations. Here I put the iteration limitation as 200, and hopefully we will kind of break out of the loop before we reach the 200 iterations, ok; that we need to see. If we do not break out of all these, then we have to increase this number to something like 500 or 1000, and then run them.

(Refer Slide Time: 05:26)

```

So, here we have a do loop this is basically similar to your for loop in C, ok, in C programming language or C plus plus, fine. So, this is similar to a for loop. Essentially we are going from i equals 1 to imax in steps of 1, ok. So, that is what we have. And then, we need to calculate what is this coefficients for the momentum equations, right.

So, you remember the momentum equation was $a_B u_B$ equals something, right, where the coefficient a_B was c_B times mod c_B times Δx , right. So, if you go down I think when you discretize the equation.

(Refer Slide Time: 06:14)

Handwritten notes on a digital whiteboard:

- Equation (2): $a_c u_c = (p_2 - p_3)$ (labeled "cell-c")
- Starred-momentum equations: $a_B u_B^* = (p_1^* - p_2^*)$ (Equation 3)
- Equation (4): $a_c u_c^* = (p_2^* - p_3^*)$ (Equation 4)
- Equation (1) - (3): $a_B u_B' = (p_1' - p_2')$
- Equation (2) - (4): $a_c u_c' = (p_2' - p_3')$
- But given $p_1 = 200$ & $p_3 = 38$; $\therefore p_1' = 0$ & $p_3' = 0$

So, these are the equations we got, right. Essentially, the coefficient here a_B is basically how much was it? a_B was $C_B \text{ mod } u_B \Delta x$, right. So, that is what we have written here.

(Refer Slide Time: 06:21)

$$C_B / u_B / u_B (x_2 - x_1) + (p_2 - p_1) = 0$$

Δx

$$C_B / u_B / \Delta x u_B + (p_2 - p_1) = 0$$

a_B

$$a_B u_B = (p_1 - p_2) \quad \text{--- ①}$$

compare $a_e u_e = \sum a_{ub} u_{ub} + 0.5 (p_p - p_e) + b_e$

cell - B.

So, $c_B \text{ mod } u_B \Delta x$ is your coefficient a_B . Similarly, a_C , $c_C \text{ mod } u_C$ times Δx , also these are the coefficients for the velocities at the staggered locations, for u_B and u_C . Now, we will not worry about this at the moment. So, these this is basically the residual I will come back to this in little while. So, before we do that, so let us not worry about this part here. So, let us look at the solution of the momentum equation. So, how do we solve for the momentum equation?

(Refer Slide Time: 06:49)

```

Momentum equation is basically you have $a_B u_B$ equals P_1 minus P_2 . So, you calculate u_B as P_1 minus P_2 by a_B , right. But of course, this does not look like that because these are under relaxed equations, ok. So, we have to look for the under relaxed equations that we have written towards the end of the formulation, so that is basically this one, ok.

(Refer Slide Time: 07:22)

Under-relax momentum equations:

Cell B: $a_B u_B^* = (P_1^* - P_2^*)$

$$\left(\frac{a_B}{\alpha_u}\right) u_B^* = (P_1^* - P_2^*) + \left(\frac{1 - \alpha_u}{\alpha_u}\right) a_B u_B^{**}$$

Cell C: $a_C u_C^* = (P_2^* - P_3^*)$

$$\left(\frac{a_C}{\alpha_u}\right) u_C^* = (P_2^* - P_3^*) + \left(\frac{1 - \alpha_u}{\alpha_u}\right) a_C u_C^{**}$$

Page 3 of 8 Layer: Layer 1

So, we are talking about a_B/α_u , u_B^* equals P_1^* minus P_2^* plus $(1 - \alpha_u)/\alpha_u$ times $a_B u_B^{**}$. So, if you want to calculate u_B^* , then you take this entire thing and then multiply that with α_u by a B, right.

That is going to give you what is u_B^* for a guess value of pressure and velocity, ok. So, that means, if you look at here, so what we have is u_B^* equals you have P_1 minus P_2 same as what we had here plus we have $1 - \alpha_u$ by α_u times $a_B u_B^*$ that is this scan it as is $(1 - \alpha_u)/\alpha_u$ times $a_B u_B^*$, ok. So, this is $a_B u_B^*$.

Now, this entire thing of from here to here, right has to be multiplied with α_u/a_B because this is coming from the left hand side, right. So, essentially you multiply with α_u/a_B on the right hand side to get u_B^* . That is what we have. Essentially, you multiply with α_u/a_B , ok.

Similarly, we write the equation for cell C that is P_2 minus P_3 plus $(1 - \alpha_u)/\alpha_u$ times $a_C u_C^*$ and the entire thing has to be multiplied with α_u and divided by a_C , ok. So, u_C equals P_2 minus P_3 these are the guess values. So, we do not have this star notation here because we know that eventually the star is basically what we have is there as the current iterate value and that is what will be used here, ok.

So, we have P_2 minus P_3 , and then plus we have u_C times a_C times u_C into $1 - \alpha_u$ by α_u and this entire thing will be now multiplied with α_u/a_C to get what is u_C value, ok. So, this is the solution of a momentum equations, right. So, once we obtain these thing we got a new values for u_B^* and u_C^* , ok, alright.

Then, let us calculate what is the value of the continuity equation. So, the continuity equation is nothing, but $A_B u_B$ minus $A_C u_C$, ok. So, let us also not worry about this residual at the moment. And we know that somehow we will kind of exit this loop if the sum of the residuals is less than the tolerance we have specified, ok.

Then, we say that the solution is converge. Now, we will come back to what is this residual, why we are using this as a check we will come back to that in little while, ok, ok. Then, once you have the star values for u_B and u_C , then you essentially go down and solve the pressure prime equation, right. What was the pressure correction equation? The pressure correction equation was P_2' equals $u_B^* A_B$ minus $u_C^* A_C$.

(Refer Slide Time: 10:00)

$$p_2' \left(\frac{A_C}{a_C} \right) + p_2' \left(\frac{A_B}{a_B} \right) = u_B^* A_B - u_C^* A_C$$

Pressure Correction Equation

$$p_2' = \frac{(u_B^* A_B - u_C^* A_C)}{\left(\frac{A_C}{a_C} + \frac{A_B}{a_B} \right)}$$

Correct velocity and pressure

$$u_B = u_B^* + u_B' = u_B^* - \frac{p_2'}{a_B}$$

$$u_C = u_C^* + u_C' = u_C^* + \frac{p_2'}{a_C}$$

So, that is P_2' equals $A_B u_B$ minus $A_C u_C$ divided by A_B by a_B plus A_C by a_C , ok. So, A_B , A_C is A_B by a_B plus A_C by a_C . So, that is what we have. So, we are solving for pressure correction equation because we have only one cell, we essentially do not have this solve for a system rather whatever we have would be fine, right. Essentially, whatever essentially we can just write it as an explicit equation, right. We do not have to solve for a system here.

(Refer Slide Time: 10:39)

end if

---- simplePorous.f90 60% L64 (F90)

```

But once we know the pressure correction, then we can correct the velocities using whatever we know, right.

(Refer Slide Time: 10:46)

$$(u_C^* + u_C') A_C - (u_B^* + u_B') A_B = 0$$

$$u_C' A_C - u_B' A_B = u_B^* A_B - u_C^* A_C$$

But $u_C' = P_2' / a_C$; $u_B' = -P_2' / a_B$ substitute

$$P_2' \left(\frac{A_C}{a_C} \right) + P_2' \left(\frac{A_B}{a_B} \right) = u_B^* A_B - u_C^* A_C$$

So, what is the relation between pressure correction and velocity correction? Once you know P_2' your u_B' would be minus P_2' / a_B that is written here and this is minus P_2' / a_B , that is u_B' and u_C' equals P_2' / a_C , right this is basically your P_2' / a_C , ok.

Then, u_B equals u_B^* plus u_B' . So, here by the time I come here u_B^* and u_B are the same, right. So, here what I am using is this is u_B^* , when you add it to u_B' the new value you would get I am still I am again storing it in u_B , ok. So, u_C gets all written. So, u_C^* plus u_C' would give me u_C , fine. Then p_2 equals p_2 plus α_p times P_2' , ok. So, this is the pressure correction equation and these are the velocity corrections and pressure correction, fine; so far so good.

Then, what do we have? Then we have to check, so basically we have done now one iteration, after one iteration we need to check whether we satisfy continuity or not. What is the continuity equation that we have? Continuity equation is basically if you go back to the problem; where is the continuity equation? Continuity equation is this one this is basically $A_C u_C$ minus $A_B u_B$, right. That is basically your $A_B u_B$ minus $A_C u_C$.

(Refer Slide Time: 11:59)

Cell-2; east-face: C; west-face: B

$$\int_B^C \frac{d}{dx} (uA) dx = 0.$$

$u_C A_C - u_B A_B = 0$ — discrete continuity eqn. for cell-2

$$(u_C^* + u_C') A_C - (u_B^* + u_B') A_B = 0$$
$$u_C' A_C - u_B' A_B = u_B^* A_B - u_C^* A_C$$

□

So, if this is satisfied by the new velocity is that is u_B and u_C that we just calculated here then that means, we got a continuity satisfying flow field, ok. So, that is the idea, ok.

--- simplePorous.f90 Bot L82 (F90)

Then, we kind of print off the values after every iteration. So, i is our iteration count and u_B and u_C are the velocities, $p2$ is the pressure. So, essentially the program the problem asked us to calculate all these 3 values. Then, we print something known as the u residual that is basically the residual coming from the momentum equation and b is nothing but is

the amount by which the flow field satisfies the continuity equation or not, ok. So, that is what we are printing after every iteration.

Now, let us get back to the u residual and c residual, ok. So, this is nothing but the u residual is nothing but, if we define something as residual if you have an equation let us say $ax = B$ then the amount by which ax is not equal to B is known as residual. So, if you take all the terms to one side that means, the residual for $ax = B$ would be $B - ax$. So, $B - ax$ if it is not equal to 0 that means, the x that you got is not satisfying the solution.

So, that means, we have to still improve the x such that $B - ax = 0$, ok. So, that is what is residual which should be used to see whether the system is satisfying the solution is satisfying the system or not, ok. So, that means, u residual is nothing, but the entire equation that you have taken to one particular site so that means, we have $a_B u_B - a_B u_B^*$ by αU . This is basically your left hand side.

So, we are taking everything in to the left hand side. So, we have on the right hand side essentially $P_1 - P_2$ plus this is all the under relaxation part. So, this entire thing, right, from here to here is the entire momentum equation which is basically taken to the left hand side. And similarly, we have we are looking at momentum what is the; what is the residual for the other cell. So, this is the residual for cell B and this is the residual for cell C, ok.

So, we are taking an absolute value of these residuals because we do not want the residual of this to be subtracted by this one, ok. So, we want to see how much is the amount by which this is not satisfied and how much is the amount by which the C cell, values are not satisfied then we calculate these two, ok.

That is the sum. So, u residual gives you the residual for cells B and C. Then, we are also updating u residual by it is absolute value of the central coefficient, that means $a_p u_p - a_p$, right, that is $u_B - a_B$ by αU . So, we are kind of normalizing this.

This is only kind of a normalization, so that like a small quantity that is coming up from these terms would not be over seen, ok. So, as a result, we are just taking the first two terms, essentially the left hand side values and we are trying to normalize whatever u residual we have computed here such that even if this comes out to be small it is with

respect to what is computed here and we would know that the value that you got here is not really small compared to this, ok. Such that we still have to kind of converge.

This is basically to take care of this is to take care of the numerical errors or the round off errors, right. So, we do not want very small values to be seen as, this is 0 or something, ok. So, this is basically. But by the time u residual goes to let us say less than the tolerance that means, we are satisfying the momentum equation, that means, the calculated u_B and u_C now satisfy the momentum equations to the up to the tolerance, ok. That is what it tells us, right.

So, that means, if we if u residual comes out to be 0 or the tolerance value that means, the u_B u_C that we have calculated now satisfy the momentum equation, right. That is what it is, ok, ok, alright, ok. And you also realize that before when I do this thing I have already used the aB as the updated values, ok. So, you may have a question here in terms of well we talked about the discrete momentum equation and the momentum equation.

So, we are talking about the discrete momentum equation in this context, but I have just updated the aB values here, ok. That means, what I use here in this equation is the latest value. So, this is the non-linear value whatever we have, right. The non-linear value would be computed here because this is the same u_B that is used to check for this, ok. So, that means, it will satisfy the same non-linear equation as such, ok. So, we have just plugged in these values, alright.

Now, let us also look at the continuity residual. So, we want to see whether the continuity value that is $A_B u_B$ minus $A_C u_C$ whether this is 0 or not, ok. Again, we are kind of taking a average of $A_B u_B$ and $A_C u_C$ and multiplying with half essentially this is to take care of the relative value of $A_B u_B$ minus $A_C u_C$, right.

This is basically the normalization here is to take care of a small values that may come which may really look small, but they are actually not small in comparison to what is the each of the flow rates, ok.

Further, we are doing this thing. Otherwise you can even check with $A_B u_B$ minus $A_C u_C$, ok, fine; essentially, these two the continuity residual and the momentum residual. This is basically what tells us that if these two together are less than the tolerance that we have specified which was some $1 \text{ E } - 6$ or something, right which was a $1 \text{ E } - 6$ here.

So, that means, if that is if both of them are less than the tolerance then the then that means, we have kind of converged to a particular solution, ok.

And then we are going to print what is the value of u_B u_C and pressure at the cell and we also going to print the b, b is nothing but the value of the continuity equation, ok. So, that is what we are going to do, alright. So, that is as far as the program is concerned.

(Refer Slide Time: 18:48)

```
kanupind@kamesh-laptop:~/Desktop/SIMPLE_PATANKAR_EX
kanupind@kamesh-laptop:~/Desktop/SIMPLE_PATANKAR_EX$ ls
a.out          simpleNozzle.f90-      simplePipeNetwork.f90-  simplePorous.f90-
simpleNozzle.f90  simplePipeNetwork.f90  simplePorous.f90
kanupind@kamesh-laptop:~/Desktop/SIMPLE_PATANKAR_EX$ gfortran simplePorous.f90
kanupind@kamesh-laptop:~/Desktop/SIMPLE_PATANKAR_EX$ ./a.out
```

Now, let us look at running this program. This is simple for us. So, I have these programs here. So, I use gfortran, gfortran simple porous dot f90 and then I would run it, ok.

```

It kind of took 55 iterations. So, the columns here are the first column is iteration the second one is u_B this is u velocity, u_C is the third column, then pressure is the 4th column, then we have the u residual and c residual, c residual is 0.

So, one thing you note is that for every iteration you see that the c residual that is the continuity equation that is the b term is always 0 or less than the tolerance, right; 0 0 1 E minus 6 0 that means, we are or simple algorithm is running driving these u_B , u_C fields through continuity satisfying field.

So, at every location that is 0, right, it is always 0. And finally, the solution is converged to u_B of 12. So, velocity is at B cell is 12 and velocity at a C cell is 15 and the pressure is 128, ok, alright. So, that is what we have. And what about the; what about the momentum equation? So, the if you look at the momentum residual initially this is somewhat large value that is the large in the sense this is 0.18 and you can see that it continuously decreases.

So, as it converges down as the u and B where p get u_B and u_C and p get updated it kind of starts decreasing and the momentum residual comes down to 1 E minus 6, ok. So, but the momentum equation eventually satisfies at this condition, but you can see that the continuity equation is always satisfied by the velocity fields that we got; ok.

And you can also see that the initial guess that we have given is kind of comes down from 15 and 12 or something and then it kind of comes down to these values, right. So, what was the initial guess again? Initial guess given was 15, 15 and 120.

```

So, initially it kind of little bit oscillates here between 11 12 and then it kind of eventually reaches a value of 12, and u_C was given a value of 15 that starts off with from 15 it comes down to 14, 13.8, then 16 and then it kind of oscillates and the pressure was given as 120, so it starts with 120 and eventually it reaches a value of 128, ok. So, these are the final values for u_B , u_C and the pressure, ok.

Now, let us see, let us not use what is given by the problem that is in the book that is basically 15, 15 120. Let us use these new values that is basically u_B is 50, u_C is 100, pressure is 1000, ok. So, remember that we have converged in 55 iterations. So, we are going to rerun this problem. So, this is gfortran simplePorous and then run it, ok, boom. So, it kind of converts this in just 61 iterations and it converts the same values that is a 12, 15 and 128. Did it start with what we have given?

Yes, it does it kind of starts, but then you can see that very immediately it kind of comes down to the velocities come down to 8, 9 and 11 or something, right.

And the pressure is very high, this is basically the pressure correction has come down from 1000 to 345 in like one step, right. And then you can again see that the momentum residual comes down and the continuity is always satisfied and so on, ok.

kanupind@kamesh-laptop:~/Desktop/SIMPLE_PATANKAR_EX$

```

So, that is the as far as the first problem is concerned, ok, alright. So, let us see, let us now look at the next problem, alright that is basically the simple porous is done.

(Refer Slide Time: 22:52)

6.5)

$$\frac{d}{dx} (\rho u A) = 0$$

$$\frac{d}{dx} (\rho u A u) = -A \frac{dp}{dx}$$

$f = 1$ everywhere;

$A_1 = 3$; $A_2 = 1$; $p_1 = 28$; $p_3 = 0$

Fluid upstream of point 1 has negligible momentum.

Calculate u_1, u_2 and p_2

So, what is the second problem? The second problem was the nozzle problem, right. So, in the nozzle problem what we have is basically there is a nozzle that is given and whose continuity and the momentum equations are given. So, the continuity equation is d by dx of $\rho u A$ equals 0, and the momentum equation is d by dx of $\rho u A u$ equals minus A

dp/dx, right. So, essentially that is what is given. And we have discretize this equation and density is given as 1 everywhere. A_A equals, A_B equals, 3 and 1, respectively.

(Refer Slide Time: 23:32)

$\rho = 1$ everywhere;
 $A_A = 3$; $A_B = 1$; $P_1 = 28$; $P_3 = 0$
 Fluid upstream of point 1 has negligible momentum.
 Calculate U_A , U_B and P_2
 Initial Guess: $U_A^* = 5/3$; $U_B^* = 5$;
 $P_2^* = 25$.
 Cell-A: $\int_1^2 \frac{d}{dx} (\rho A u) dx = \int_1^2 -A \frac{dp}{dx} dx$

And the pressure boundary condition is given that is 28 and 0, right. And we formulated this and the initial guess is also given, ok.

(Refer Slide Time: 23:38)

```

program main
implicit none
integer :: it, itmax
real :: AA, AB, p1, p3
real :: UA, UB, p2
real :: FA, FB
real :: dA, dB, b
real :: p2prime, uAprime, uBprime
real :: alphaU, alphaP
real :: u_residual, c_residual
real :: tolerance

! given values
! boundary conditions)
p1 = 28.0
p3 = 0.0
! geometry
AA = 3.0
AB = 1.0

! initial guess
UA = 5.0/3.0
UB = 5.0
p2 = 25.0
    
```

So, let us see what is the second problem looks like simple nozzle. So, again we have these are the definitions declaration of the variables that is we have AA, AB, these are the cross sectional areas and then in P_1 and P_3 are the pressures, and then u_A , u_B are the velocities,

right, P_2 is the pressure essentially we have to calculate what are these values, ok. And then F_A are the flow rates, F_A and F_B ; d_A d_B are the coefficients that we get in the prime equations, ok.

Similarly, we have p_2 prime, u_A prime and u_B' these are the velocity and the pressure corrections and then we have α_U and α_P , ok, alright. So, if you see the given boundary conditions are P_1 equals 28, P_3 equals 0, right. These are already given. So, P_1 equals 28, P_3 equals 0 that is already given and the geometry is given as cross sectional areas let us 3 and 1, right. This is 3 and this is 1, A_A is 3, A_B is 1 and the initial guess is given as five-thirds for u_A , u_B equals 5.

(Refer Slide Time: 24:38)

```

emac@kamesh-laptop
File Edit Options Buffers Tools F90 Help
! boundary conditions)
p1 = 28.0
p3 = 0.0
! geometry
AA = 3.0
AB = 1.0

! initial guess
uA = 5.0/3.0
uB = 5.0
p2 = 25.0

tolerance = 1.0e-6
alphaP = 0.8
alphaU = 0.8
itmax = 100
!under relaxation parameters
!maximum no. of iterations

do it = 1, itmax

! calculate momentum coefficients
FA = uA*AA
FB = uB*AB
dA = AA/FA
dB = AB/FB

```

So, we take this as 5, and P_2 is 25, ok. So, this is 25, ok, alright. That is the initial guess for pressure, ok. The tolerance value is 1 E minus 6. Again, I set it to 1 E minus 6 bar equations to kind of converge. Then we have α_P equals 0.8, α_u equals 0.8, these are basically your under relaxation parameters, ok.

And then again I said these are the iteration max is maximum number of iterations before which we want to we hope to come out of the loop. So, this is the loop. So, do iteration equals 1 to it max. So, we calculate the momentum coefficients, ok.

(Refer Slide Time: 25: 32)

$F_2 \geq 0 ; u_2 = u_A$
 $F_1 \geq 0 ; u_1 = u_{\text{upstream}} ; \text{but } F_1 \approx 0 \text{ (given)}$
 $F_2 u_A = A_A (P_1 - P_2)$
Cell + B : $\int_2^3 \frac{d}{dx} (\rho A u) dx = \int_2^3 -A \frac{dp}{dx} dx$
 $F_3 u_B - F_2 u_2 = A_B (P_2 - P_3)$

So, the momentum coefficients are basically we have if you go back to the problem what are the coefficients for momentum? Basically, your F_2 that is nothing, but your F_A , right, so ok. For the cell A we have F_A and F_B , right.

(Refer Slide Time: 25:36)

$(\rho u A)_B - (\rho u A)_A = 0$
 $F_B - F_A = 0 \Rightarrow F_A = F_B$
 $F_2 = F_A = F_B = F_1 = F_3$
 Cell: A : $F_A u_A = A_A (P_1 - P_2)$
 Cell: B : $F_B u_B - F_A u_A = A_B (P_2 - P_3)$
 starred-equations $F_A u_A^* = A_A (P_1^* - P_2^*)$
 $F_B u_B^* = F_A u_A^* + A_B (P_2^* - P_3^*)$

So, we look at what is F_A . F_A is your is basically u_A times A_A , right velocity times area and then we have ρ equals 1 similarly F_B is $u_B A_B$. So, that is the coefficients here.

(Refer Slide Time: 25:58)

$$F_A u_A' = A_A (P_1' - P_2')$$

$$F_B u_B' = F_A u_A' + A_B (P_2' - P_3')$$
 (SIMPLE)

$$u_A' = \left(\frac{A_A}{F_A}\right) (P_1' - P_2') = -d_A P_2' ; \quad d_A = \left(\frac{A_A}{F_A}\right)$$

$$u_B' = \left(\frac{A_B}{F_B}\right) (P_2' - P_3') = d_B P_2' ; \quad d_B = \left(\frac{A_B}{F_B}\right)$$

$$u_A' = -d_A P_2'$$

Then, d_A which we get here, this we defined as d_A that is A_A by F_A . So, we calculate we assign d_A equals A_A by F_A and d_B equals A_B by F_B , right. So, we have those two values as well.

(Refer Slide Time: 26:07)

```

alphaP = 0.8
alphaU = 0.8
itmax = 100

do it = 1, itmax

! calculate momentum coefficients
FA = UA*AA
FB = UB*AB
dA = AA/FA
dB = AB/FB

! calculate residual for the momentum equations
u_residual = abs(FA*UA/alphaU - AA*(p1 - p2) - FA*UA*(1.0 - alphaU)/alphaU) + &
& abs(FB*UB/alphaU - FA*UA - AB*(p2 - p3) - FB*UB*(1.0 - alphaU)/alphaU)
u_residual = u_residual/(abs(FA*UA/alphaU) + abs(FB*UB/alphaU))

! solve momentum equation
UA = (AA*(p1 - p2) + FA*UA*(1.0 - alphaU)/alphaU)*alphaU/FA
UB = (FA*UA + AB*(p2 - p3) + FB*UB*(1.0 - alphaU)/alphaU)*alphaU/FB

! calculate residual for the continuity
c_residual = abs(UA*AA - UB*AB)/(0.5*(abs(UA*AA) + abs(UB*AB)))

if ((u_residual + c_residual) < tolerance) then

```

And then we use the this is again the residuals. So, basically taking the entire momentum equation to one side; this is what we have, ok. We will come back to this little later.

(Refer Slide Time: 26:31)

The image shows a digital whiteboard with the following handwritten equations:

Cell A: $F_A u_A^* = A_A (P_1^* - P_2^*)$

$\Rightarrow \left(\frac{F_A}{\alpha_u}\right) u_A^* = A_A (P_1^* - P_2^*) + \left(\frac{1-\alpha_u}{\alpha_u}\right) F_A u_A^{**}$

Cell B: $F_B u_B^* = F_A u_A^* + A_B (P_2^* - P_3^*)$

$\left(\frac{1}{\alpha_u}\right) F_B u_B^* = F_A u_A^* + A_B (P_2^* - P_3^*) + \left(\frac{1-\alpha_u}{\alpha_u}\right) F_B u_B^{**}$

So, what is the momentum equation? Momentum equation is we have to look for the under relaxed equation that we have written that is basically this value, right that is your u_A^* equals A_A times P_1^* minus P_2^* that is A_A times P_1^* minus P_2^* plus this is basically your under relaxation component that is 1 minus α_u by α_u times $F_A u_A$.

And then this entire thing has to be entire equation has to be multiplied with α_u times F_A , multiply with α_u divided by F_A to get what is u_A^* , ok. So, that is how you get the u_A^* . And u_B^* is also similar u_B^* has basically $F_A u_A$ that is your $F_A u_A$ here, right, here. Then the second term is A_B times P_2 minus P_3 . So, that is your A_B times P_2 minus P_3 plus this thing is again coming from the under relaxation.

And what we have is a multiply this with this entire thing with α_u by divided by F_B to get value of $F_B u_B^*$, ok. So, that is u_B^* equals $F_A u_A$ plus A_B times P_2 minus P_3 plus the under relaxation component and then we have multiplication with α_u times F_B , ok, alright, ok. So, just got it here, ok; so, this is your u_B^* , fine.

Then, again the continuity equation. What was the continuity equation? Continuity equation was; continuity equation was F_B minus F_A , right that means, ρ equals 1 . So, this is $u_B A_B$ minus $u_A A_A$, right. So, if your continuity residual would be $u_A A_A$ minus $u_B A_B$, again I am dividing with whatever is the continuity value average value such that this becomes kind of normalized, ok.

Similarly, now we can understand how this residual is calculated. This is the absolute value for cell A, ok. So, this is basically the absolute value for cell A, right. So, this is $F_A u_A$ by α_U . This is the left hand side equation, left hand side part of the equation and this is the right hand side brought to the left hand side, right.

So, essentially we have this is for cell A and we take the absolute value similarly we take the other value that is for the B cell, we have $F_B u_B$ by α_U minus $F_A u_A$ all these things basically this is your first cell B, ok.

And again we use, we normalize with the central coefficient that is $F_A u_A$ by α_U and $F_B u_B$ by α_U , to basically get to normalize this value, ok. So, that is what we are doing.

(Refer Slide Time: 29:13)

  :... simpleNozzle.f90 24% L34 (F90)

```

So, that means, basically this is to normalize the residual value, such that it is not going to be very small or very large, ok. So, that is the residual for velocity. So, that means, if we go back to the algorithm we started off with calculating the coefficients, then we computed this all the momentum equations then we have to solve for the pressure correction equation. So, P'_2 is basically coming from our equation.

(Refer Slide Time: 29:42)

The image shows a handwritten derivation in a digital journal application. At the top, the equation $(d_B A_B + d_A A_A) P_2' = (u_A^* A_A - u_B^* A_B)$ is written. Below it, the pressure correction is boxed as $P_2' = \frac{(u_A^* A_A - u_B^* A_B)}{(d_A A_A + d_B A_B)}$. At the bottom, the velocity correction formulas are given: $u_A = u_A^* + u_A' = u_A^* - d_A P_2'$ and $u_B = u_B^* + u_B' = u_B^* + d_B P_2'$. The journal interface includes a toolbar with drawing tools and a status bar at the bottom showing 'Page 5 of 8 Layer: Layer 1'.

What was P_2' ? P_2' was, this guy, right this is P_2' equals $u_A^* A_A$ minus $u_B^* A_B$ upon $d_A A_A$ plus $d_B A_B$, ok. So, that is what we have in the program. This is P_2' equals $u_A^* A_A$ minus $u_B^* A_B$ divided by $d_A A_A$ plus $d_B A_B$, ok. So, that is what we have. Again, we have only one cell. So, we do not have to solve for a system. We just plug in what is the value of u_A^* and u_B^* and calculate what is P_2' , alright, ok.

Then, once you have the pressure correction value, then you can use pressure correction to correct the velocities, right. So, what is the formula for correcting the velocity corrections? Velocity corrections are basically u_A' equals minus $d_A P_2'$, so that is u_A' equals minus $d_A P_2'$ and u_B' equals plus $d_B P_2'$, right that is what we have from here, u_B' equals plus $d_B P_2'$.

(Refer Slide Time: 30:23)

Handwritten mathematical derivations in a journal window:

$$u_B' = \left(\frac{A_B}{F_B}\right) (p_2') = d_B p_2'; \quad d_B = \left(\frac{A_B}{F_B}\right)$$

$$u_A' = -d_A p_2'$$

$$u_B' = +d_B p_2'$$

From the continuity equation: $F_B - F_A = 0$

$$F_B' - F_A' = F_A^* - F_B^*$$

$p=1;$

$$u_B' A_B - u_A' A_A = F_A^* - F_B^*$$

So, we correct the velocities, then we can update the velocity u_A as u_A^* plus u_A prime and u_B as u_B^* plus u_B' and the pressure as P_2 equals P_2 plus $\alpha_p P_2'$, ok. Again, we check for convergence. So, this is basically whether continuity is satisfied or not.

So, we look for $u_A^* A_A$ minus $u_B^* A_B$, this is the value of our continuity equation, right. So, with whatever corrected value, so this should satisfy continuity at each and every iteration, ok. Then, we print out the b value that is the continuity value u_A , u_B let us print out this at the end, ok. So, that means, we print out what is u_A , u_B , and pressure, and b, ok.

(Refer Slide Time: 31:37)

```

exit
end if

! solve pprime equation
p2prime = (uA*AA - uB*AB)/(dA*AA + dB*AB)

! correct velocities and pressure
uAprime = -dA*p2prime
uBprime = +dB*p2prime
uA = uA + uAprime
uB = uB + uBprime
p2 = p2 + alphaP*p2prime

! check whether continuity is satisfied
b = uA*AA - uB*AB

!write(*, *) 'It, uA, uB, p2, u_residual, c_residual are =', it, uA, uB, p2, u_residual, c_residual

write(*, *) uA, uB, p2, c_residual, b

end do

end program main

```

Now, if you want you can also print out what is the c residual, alright. So, the c residual can also be printed, ok. So, that is the overall algorithm, and then we hope to exit this before the iterations finish through this condition, right. So, essentially this is the condition, this is basically tells you that if your residual some of the residuals is less than the tolerance, then we say we have reached the convert solution and the solution is blah blah, that is u_A u_B and P_2 and then we exit, ok.

So, but we have to make sure that the we do not run out of the iterations as such, ok. Let us also print what is the iteration count here. So, that is i, right, ok. So, we should know that we have not reached more than 100, ok. Let us see if we can run this program. So, this is simple nozzle. So, gfortran is simple nozzle, so problem here has no implicit type, ok. So, this is there is no i here, this is basically iteration, ok, alright, ok.

So, we can of course, again play with these values the initial guess values and see whether the program runs or not, ok. I leave that for you to do, ok. So, that is about the second problem that is in flow through a nozzle, ok, alright. Now, let us look at the third problem that we formulated in the last class that is basically now in these both problems we have non-linearity, right.

In the first problem, in the porosity case we have nonlinearity in the source term. In the second case, we have non-linearity through the convection term, right. So, that is why we had to do so many iterations like some 20 iterations or so, fine.

(Refer Slide Time: 34:16)

6.7) $Q = C \Delta p$

$\Delta p =$ pressure drop over the length of the pipe

$C =$ Hydraulic Conductance

$p_1 = 275; p_2 = 70$

$p_4 = 0; p_5 = 40; Q_F = 40$

$C_A = 0.4; C_B = C_D = C_F = 0.2$

Now, let us move on to the third problem. Third problem was a flow through a residential pipe network, right. So, essentially we have Q is given as C times Δp , where C is the hydraulic conductance, Δp is the pressure drop over the length of the pipe. And what we were given is we were given this pipe network with the flow rates and the pressure stored at the 1, 2, 3, 4, all the way to 7 and the velocity stored at A, B all the way to F , right.

(Refer Slide Time: 34:46)

$C_A = 0.4; C_B = C_D = C_F = 0.2$

$C_C = C_E = 0.1$

Calculate $p_3, p_6, Q_A, Q_B, Q_C, Q_D, Q_E$?

 Cell - A: $\int_1^3 Q dx = \int_1^3 (C \Delta p) dx$

$Q_A (\Delta x) = C_A (\Delta p) (\Delta x)$

$Q_A = C_A (p_1 - p_3) \quad | \quad Q_A = C_A (p_1' - p_3')$

And we were also given some of these pressures that is P_1 is given as 275, P_2 is given as 70, P_4 as 0, P_5 as 40 and so on and Q_F as 40, ok, alright. So, and also the of course, the

values of all the hydraulic conductance are given C_A to C_F , and we were ask to calculate what is the pressure at this P_3 and P_6 ; and what is the flow rate through Q_A, Q_B all the way to Q_E , ok. So, we have to calculate what are all the flow rates.

(Refer Slide Time: 35:15)

Handwritten equations for flow rates in a network, divided into "stored equations" and "prime equations".

Stored equations:

$$Q_A = C_A (P_1 - P_3)$$

Similarly

$$Q_B = C_B (P_3 - P_2)$$

$$Q_C = C_C (P_4 - P_3)$$

$$Q_D = C_D (P_5 - P_6)$$

$$Q_E = C_E (P_5 - P_6)$$

$$Q_F = C_F (P_6 - P_2)$$

prime equations:

$$Q_A' = C_A (P_1' - P_3')$$

$$Q_B' = C_B (P_3' - P_2')$$

$$Q_C' = C_C (P_4' - P_3')$$

$$Q_D' = C_D (P_5' - P_6')$$

$$Q_E' = C_E (P_5' - P_6')$$

$$Q_F' = C_F (P_6' - P_2')$$

We have formulated the problem using finite volume method, and we said these are the momentum equations; these are the corrections, pressure corrections in terms of the flow corrections.

(Refer Slide Time: 35:24)

Handwritten continuity equation for cell-3:

Continuity equation: Cell-3: $Q_A + Q_C - Q_B - Q_D = 0$

$$Q_A' + Q_C' - Q_B' - Q_D' = Q_B^* + Q_D^* - Q_A^* - Q_C^*$$

$$C_A (P_1' - P_3') + C_C (P_4' - P_3') - C_B (P_3' - P_2') - C_D (P_5' - P_6') = Q_B^* + Q_D^* - Q_A^* - Q_C^*$$

$$P_3' (-C_A - C_B - C_C - C_D) + P_6' (C_D) = Q_B^* + Q_D^* - Q_A^* - Q_C^*$$

(Refer Slide Time: 35:31)

Cell-6:

$$Q_D + Q_E - Q_F = 0$$
$$Q_D^1 + Q_E^1 - Q_F^1 = Q_F^* - Q_D^* - Q_E^*$$
$$C_D(p_3^1 - p_6^1) + C_E(p_6^1 - p_3^1) - 0 = Q_F - Q_D^* - Q_E^*$$
$$p_3^1(C_D) + p_6^1(-C_D - C_E) = Q_F - Q_D^* - Q_E^* \rightarrow (2)$$

Solve for p_3^1 and p_6^1 ...

$$Q_A = Q_A^* + Q_A^1 = Q_A^* - C_A p_3^1$$

Then, we wrote the continuity equation or the mass conservation equation, and we said that the continuity equation will give you one equation in terms of P_3^1 and P_6^1 and another equation at junction 6 as another equation in terms of P_3^1 and P_6^1 , with the right hand side as known values, ok. Now, we have two equations and two unknowns, right P_3^1 and P_6^1 , alright.

Let us look at the corresponding code. So, the corresponding code is a simple pipe network, ok.

(Refer Slide Time: 35:58)

```
program main
  implicit none
  integer :: it
  real :: p1, p2, p3, p4, p5, p6
  real :: QA, QB, QC, QD, QE, QF
  real :: CA, CB, CC, CD, CE, CF
  real :: a1, b1, d1, a2, b2, d2 !to solve the pressure-correction equation
  real :: p3prime, p6prime

  ! Given values
  p1 = 275.0
  p2 = 270.0
  p4 = 0.0
  p5 = 40.0

  QF = 20.0

  CA = 0.4
  CB = 0.2
  CC = 0.1
  CD = 0.2
  CE = 0.1
  CF = 0.2

  ! guess p3 and p6
end program
```

So, page up, ok. So, again this is the main program. So, these are all the variables that we define, P_1 to P_6 the pressures, Q_A to Q_F the flow rates, C_A to C_F the hydraulic conductance values, right. And then a_1 , b_1 , d_1 , a_2 , b_2 , d_2 are basically the coefficients that are written.

These are basically these are to solve the we had two equations and two unknowns, right, so to solve the pressure correction, ok, pressure correction equation, right. So, these are the coefficients we will see them later. And then of course, these are the P'_3 and P'_6 are the pressure, correction values at 3 and 6 locations, ok, fine.

Then, what was the initial; what was the given values? Given values for P_1 P_2 are given as 275 and 270. So, if you look at the values P_1 is 275, P_2 is 270, P_4 is 0, all right, P_4 is 0, P_5 is 40, and then Q_F is 20, right, Q_F is 20. Then, C_A to C_A to C_F all these values I have written out here, C_A , C_B , all the way to C_F , C_F is 0.2, ok. So, these are the hydraulic conductance values.

-:--- simplePipeNetwork.F90 23% L37 (F90)
```

So, if we look at the equations what we had was, ok; so, the first step is write the solve the momentum equation. Momentum equations are Q_A equals C_A times P_1 minus P_3 . So, that

is what we have. This is Q_A equals C_A times P_1 minus P_3 . And similarly, Q_B equals C_B times P_3 minus P_2 that is the other equation. Similarly, Q_C equals C_C times P_4 minus P_3 that is what we have here; Q_C is C_C times P_4 minus P_3 and Q_D and Q_E , ok.

So, with the initial guess values for pressure or the using the given values for pressure we calculate what is the flow rates, ok. Then, what we do is basically we got these flow rates, then we have to solve the pressure correction equation, ok. In order to do the pressure correction equation, we realize that we had two equations set two unknowns, ok. So, what we do is we basically write out the coefficients. So, I am writing these coefficients as basically a_1 , b_1 and d_1 and sum a_2 , a_2 , b_2 and d_2 , right.

So, that I can solve two equations and two unknowns; so, a_1 is basically you are C_A , C_A plus C_B plus C_C plus C_D with all minus. So, that is what I have here, right. a_1 is minus of a C_A plus C_C plus C_B plus C_D . Similarly, b_1 is your C_D , ok. And d_1 is your right hand side that is $Q_B^* - Q_D^* - Q_A^* - Q_C^*$, ok. So, these values are given. These are now taken from here.

Then, for the second equation we have this coefficient we are writing it as a_2 . So, a_2 is C_D , b_2 is minus C_D minus C_A , and d_2 is $Q_F - Q_D^* - Q_E^*$, ok. So, that is the value.

! solve pressure correction equation
! to obtain p3prime and p6prime

a1 = -(CA + CC + CB + CD)
b1 = CD
d1 = QB + QD - QA - QC

a2 = CD
b2 = - CD - CE
d2 = QF - QD - QE

! instead of using GS; we are just directly solving
! the two equations here

p3prime = (d1*b2 - d2*b1)/(a1*b2 - a2*b1)
p6prime = (a2*d1 - a1*d2)/(a2*b1 - a1*b2)

! correct pressure
p3 = p3 + p3prime
p6 = p6 + p6prime

! correct flow rates
QA = QA - CA*p3prime
QB = QB + CB*p3prime
QC = QC - CC*p3prime

simplePipeNetwork.F90 34% L59 (F90)
Mark set

```

Then, of course, I can basically I have two equations two unknowns I can write what is P'_3 in terms of these coefficients. So, I would just eliminate the variables and calculate this as

$d_1 b_2$ minus basically a proper proportion of these $d_1 b_2$ minus $d_2 b_1$ by $a_1 b_2$ minus $a_2 b_1$ that gives me what is P'_3 . Similarly, I can write down what is P'_6 as a $d_1 b_2$ minus $a_1 b_2$ upon a $d_2 b_1$ minus $a_2 b_1$, ok.

So, basically we are just solving, instead of using Gauss-Seidel we are just directly solving the two equations here, ok, alright. So, that is what we do. Then, once you obtain what is P'_3 and P'_6 we can just correct them, right. So, basically correct P_3 equals P_3^* plus P'_3 , similarly P_6 equals P_6^* plus P'_6 , ok. So, we have done that.

Then, what do we do? Then we correct the flow rates that is Q_A equals Q_A^* plus Q'_A , but we know that what is Q'_A . Q'_A is nothing but, Q'_A is nothing, but C_A times this is 0 minus P'_3 . So, this is minus C_A times P'_3 .

Similarly, we know we can correct what is Q_B ; Q_C that is Q_C minus C_C times P'_3 because P'_4 is 0, because P_4 is given as a pressure boundary condition and Q_D equals Q_D^* plus Q'_D that is C_D times P'_3 minus P'_6 that is this value. Then, Q_E equals Q_E plus Q_E^* plus Q'_E Q'_E is C_A times P'_3 is 0.

So, this is minus $C_A P'_6$, ok. So, this is minus $C_A P'_6$, fine. Then, we print the continuity equation. Continuity equation is two equations, one for each cell junctions 3 and 6. So, this is Q_A plus Q_C minus Q_B minus Q_D and the second junction at 6 is Q_D plus Q_E minus Q_F ,

ok. Then, we print the residuals for the momentum equations, right. These are the residuals for the momentum equation.

kanupind@kamesh-laptop:~/Desktop/SIMPLE_PATANKAR_EX$
```

So, let us try to run this. This is simple pipe network. So, `gfortran simplePipeNetwork, dot slash a dot`, ok. So, what do we see here? We see that in just one iteration the everything got converged, right because it satisfies continuity after the corrections, this is basically the continuity values. Both are of the order of 10^{-6} and the momentum residuals are also satisfied.

So, that means, everything is satisfied after one iteration, right. And the pressure came out as 280, and the flow rates as 30 minus 14 minus 20, 24 minus 4, right. And although we have done another iteration this is not required because the values actually do not change, right. These values are the same as these values where we get here. This is because only one correction is required because the problem is linear, right. There is no non-linearity.

As a result, the velocity corrections and pressure corrections that we have satisfy both the continuity and momentum equations exactly after just one iteration, ok. So, that is why without any problems without any having more iterations we were able to converge these in just one iteration, ok.

```

So, what I do is, what I will do is I will share these programs with you on Moodle. So, you can download them, and then run them, kind of learn from them, and then they probably will be useful later on with an assignment or something like that, ok, alright.

Then, I will stop here. I will talk to you in the next lecture. If you have any questions send them through email to me, ok, alright.

Thank you.
