**Lecture - 52**  
**Oscillator Algebra**

Okay so today I am going to use the oscillator algebra applications whatever we learnt in oscillators to solve problem which we have done explicitly using the position space wave function for a particle in a magnetic field and then later on we will study angular momentum algebra using this oscillator approach okay. So that is the plan. If you recall, we did this in the last lecture last week.

**(Refer Slide Time: 01:07)**

The harmonic oscillator we had a with a dagger is identity, this is what we will call it as an oscillator algebra and  $J_x$  with  $J_y$  is  $i\hbar$  cross  $J_z$ . This is what we will call it as an angular momentum algebra. So the number operator for the oscillator algebra is an eigenstate  $n$  with the number operator with eigenvalue  $n$  and with the number operator the two ladder operators has this commutator relation.

And from this we can determine  $a$  on  $n$  is square root  $n$  times  $n-1$ , it is a lowering operator and similarly  $a^\dagger$  is the raising operator okay. So using this oscillator algebra, we would like to solve this problem of particle in a magnetic field and then can we use this oscillator algebra to determine the spectrum for the angle of momentum also. So this is the motivation for today's lecture okay.

(Refer Slide Time: 02:08)

**Charged particle in a magnetic field  $B$  along  $z$**

- Hamiltonian  $\hat{H} = \frac{\Pi_x^2}{2m} + \frac{\Pi_y^2}{2m} + \frac{p_z^2}{2m}$  where  $\Pi_i = (p_i - eA_i)$ .

$$\hat{N}|n\rangle = a^\dagger a |n\rangle = n|n\rangle$$

$$\hat{H}|n\rangle = (n + 1/2)\hbar\omega_c |n\rangle$$

- We have derived the operation of ladder operators on  $|n\rangle$  as follows:

$$a|n\rangle = \sqrt{n}|n-1\rangle$$

$$a^\dagger|n\rangle = \sqrt{n+1}|n+1\rangle$$

Lecture 21: Oscillator algebra applications

Recall the particle in a magnetic field. Let us take the magnetic field along z-direction. So this is given by this Hamiltonian which is  $\pi_x \times \pi_y$  are in terms of it is proportional to momentum minus the shift due to the vector potential. It  $\pi_i - A_i$  and as I said already recall the number operator eigenstate is the simultaneous eigenstate of the Hamiltonian with eigenvalue proportional to  $\hbar \omega_c$ .

So in this problem this is for a general harmonic oscillator. What does  $\omega_c$  will correspond here we will figure it out. So the ladder operator in any harmonic oscillator has this property as I have already discussed for you.

(Refer Slide Time: 02:58)

**Energy eigenvalues?**

- Recall we took trial wavefunction and a choice for vector potential giving us a shifted harmonic oscillator potential in the  $y$  direction leading to Landau levels.

$$E_{n,k_z} = (n + 1/2)\hbar\omega_c + \frac{\hbar^2 k_z^2}{2m}$$

where  $\omega_c = \frac{eB}{m}$

- How to we obtain the eigenvalues using ladder operators?
- Evaluate the following commutators

$$[\Pi_x, \Pi_y], \quad \hat{p} \cdot \hat{A}(\vec{r}) - \hat{A}(\vec{r}) \cdot \hat{p}$$

Lecture 21: Oscillator algebra applications

And in one of the earlier lecture, I explicitly went through a trial wave function and a choice of a vector potential and derived the energy spectrum to have the frequency with which we will call it as a cyclotron frequency and it is like a free particle along the z-direction. So this is what we called as Landau levels. How do we obtain such an energy eigenvalues using these ladder operators which we saw in the harmonic oscillator?

So couple of things I want you to work it out is commutator of the x component with y component for  $\pi_x$  and  $\pi_y$  and similarly we know that  $p$  with  $A$  and  $A$  with  $p$  that order really matters,  $p \cdot A$  is not same as  $A \cdot p$ . So just to take you on how.

**(Refer Slide Time: 03:56)**

The image shows a greenboard with handwritten mathematical expressions. At the top right, there is a logo for CDEE, IIT Bombay, with the text 'EP 228 L 2.4'. At the bottom left, there is a logo for NPTEL. The equations written on the board are:

$$\pi_x = p_x - eA_x(x, y, z)$$

$$\pi_y = p_y - eA_y(x, y, z)$$

$$[p_x, A_x(\vec{r})] = -i\hbar \frac{\partial A_x(\vec{r})}{\partial x}$$

$$[p_x, f(x)] = -i\hbar \frac{\partial f(x)}{\partial x}$$

$$[p_y, A_y(\vec{r})] = -i\hbar \frac{\partial A_y(\vec{r})}{\partial x}$$

In general, the potentials are functions of positions. So  $\pi_x$  is  $p_x - eA_x$  which is a function of positions. So if you take  $p_x$  with  $A_x$  that commutator is not 0, it will be  $-i\hbar$  cross  $\text{del}/\text{del } x$  of  $A_x$ . This is because you know  $x, p$  commutator,  $p_x$  with  $x$  is nonzero and if you have any function of  $x$ , it should be  $\text{del}/\text{del } x$  of  $f$  of  $x$ . Similarly, if you try to find the  $p_x$  commutator with  $A_y$ , you are expected to be  $-i\hbar$  cross  $\text{del}/\text{del } x$  of  $A_y$ .

**(Refer Slide Time: 04:44)**

$$\vec{B} = B \hat{e}_z$$

$$[\pi_x, \pi_y] = -e [p_x, A_y] +$$

$$-e [A_x, p_y]$$

$$= i\hbar e (\vec{\nabla} \times \vec{A})_z = i\hbar e B$$

$$[p_x, p_y] = 0$$

$$[A_x(\vec{r}), A_y(\vec{r})] = 0$$

$$[\pi_x, \pi_y] = i\hbar e B$$

$$\pi_x' = \frac{\pi_x}{\sqrt{i\hbar e B}}$$

$$\pi_y' = \frac{\pi_y}{\sqrt{i\hbar e B}}$$

$$[\pi_x', \pi_y'] = 1$$

$$[p_x, A_y] = -i\hbar \frac{\partial A_y}{\partial x}$$

$$[A_x, p_y] = i\hbar \frac{\partial A_x}{\partial y}$$

So if you want to work out using these data, use these data and let us work out for a particle in a magnetic field along z-direction magnitude is B along z-direction, try to compute the pi x with pi y, the nonzero commutators are Px with Ay and Ax with Py and that gives us a constant okay. So the pi x with pi y is not 0 like Px and Py but this is nonzero and it is the constant depends on the magnetic field.

You can normalize the pi x by this normalization, so that you can make pi x prime with pi y prime to be identity. So this is what I said in the earlier lecture, earlier slide Px with Ay is del/del x of Ay and Px with Py is del/del y of Ax and if we use that here you get curl of A which is nothing but it is a (()) (05:47).

**(Refer Slide Time: 05:51)**

$$\hat{P} \cdot \hat{A} - \hat{A} \cdot \hat{P}$$

$$[p_x, A_x] = -i\hbar \frac{\partial A_x}{\partial x}$$

$$\{\hat{P}\hat{A} - \hat{A}\hat{P}\} = -i\hbar \nabla \cdot \vec{A}$$

Coulomb gauge  $\nabla \cdot \vec{A} = 0$

$$\vec{A} \rightarrow \vec{A} + \nabla \chi$$

$$H = \frac{\pi_x^2}{2m} + \frac{\pi_y^2}{2m} + \frac{p_z^2}{2m} \rightarrow H'$$

Similarly, the  $\mathbf{P} \cdot \mathbf{A} - \mathbf{A} \cdot \mathbf{P}$  with  $A_x$  is  $\text{del}/\text{del } x$  of  $A_x$ .  $\mathbf{P} \cdot \mathbf{A} - \mathbf{A} \cdot \mathbf{P}$  is nothing but  $-i\hbar$  cross divergence of  $\mathbf{A}$  or  $\text{del} \cdot \mathbf{A}$ . We can choose a gauge which is known to us as Coulomb gauge where  $\text{del} \cdot \mathbf{A}$  is 0 and recall that the vector potential can be changed from by a gauge transformation by a gradient of  $\chi$  but this change will not affect your magnetic field, magnetic field will remain same under this gauge transformation but what happens to the Hamiltonian. Hamiltonian can in principle change to  $H$  bra.

**(Refer Slide Time: 06:42)**

**Energy eigenvalues?**

- Recall we took trial wavefunction and a choice for vector potential giving us a shifted harmonic oscillator potential in the  $y$  direction leading to Landau levels.

$$E_{n,k_z} = (n + 1/2)\hbar\omega_c + \frac{\hbar^2 k_z^2}{2}$$

where  $\omega_c = \frac{eB}{m}$

- How to we obtain the eigenvalues using ladder operators?
- Evaluate the following commutators

$$[\Pi_x, \Pi_y], \quad \hat{\mathbf{p}} \cdot \hat{\mathbf{A}}(\vec{r}) - \hat{\mathbf{A}}(\vec{r}) \cdot \hat{\mathbf{p}}$$

- Take a gauge (Coulomb gauge)  $\nabla \cdot \mathbf{A} = 0$ .
- In this gauge,

$$[\Pi_x, \Pi_y] = i\hbar eB$$

this is similar to  $[x, p_x]$  commutator which helped to write operators  $a, a^\dagger$

**CDEEP**  
IIT BOMBAY

NPTEL

LECTURE 21: Oscillator algebra applications

So we worked out  $\pi_x$  and  $\pi_y$  and  $\mathbf{P} \cdot \mathbf{A}$  and  $\mathbf{A} \cdot \mathbf{P}$ . Take the gauge which is the Coulomb gauge and if this gauge  $\pi_x \pi_y$  is  $i\hbar$  cross  $eB$  and this is similar to our familiar  $x, p_x$  commutator which helped us to write  $a$  and  $a^\dagger$  okay. So that is what is the motivation, just like we had in the harmonic oscillator  $x^2 + p_x^2$  putting  $n, \omega$  everything to be 1 here.

We have a  $\pi_x^2$  and  $\pi_y^2$  and similar to  $x, p_x$  commutator which is constant and nonzero we have  $\pi_x$  with  $\pi_y$  to be nonzero and a constant. So using this we can try to construct a new ladder operators involving  $\pi_x$  and  $\pi_y$ .

**(Refer Slide Time: 07:38)**

• We do a similar thing here

$$\hat{b} = \frac{\Pi_x + i\Pi_y}{\sqrt{2eB\hbar}}$$

$$\hat{b}^\dagger = \frac{\Pi_x - i\Pi_y}{\sqrt{2eB\hbar}}$$

$$\hat{b}^\dagger \hat{b} = \frac{1}{2eB\hbar} \{ \Pi_x^2 + \Pi_y^2 + i[\Pi_x, \Pi_y] \}$$

$$H = (b^\dagger b + 1/2) \frac{\hbar eB}{m} + \frac{p_z^2}{2m}$$

• It is similar to solving harmonic oscillator with angular frequency

$$\omega_c = \frac{eB}{m}$$

To determine the position space wavefunctions, we need to find the ground state wavefunction for the vector potential  $\mathbf{A}(\vec{r})$

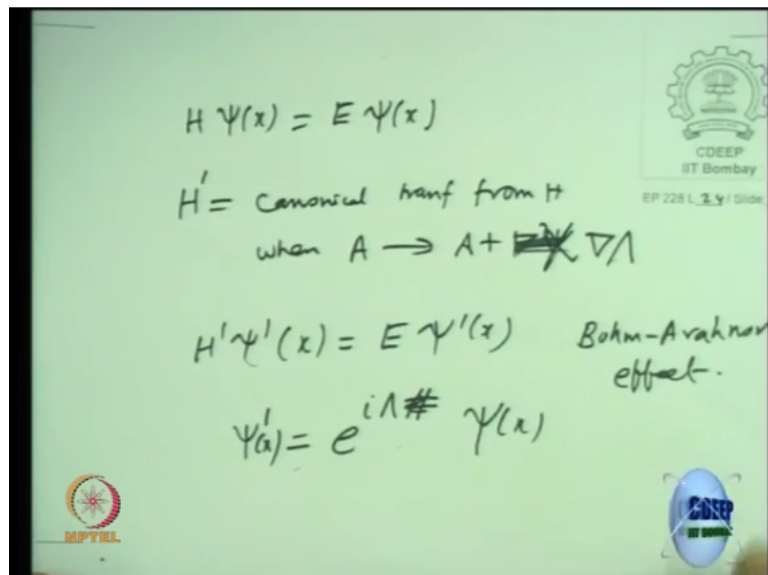

January 2016 | EP718: Quantum Mechanics I | Lecture 24: Oscillator algebra applications

So this is what we do here. We try to take the ladder operators as  $\pi_x + i\pi_y$  with this normalization and similarly the conjugate Hermitian conjugate of that and if you try to find the commutator, please check the commutator and you will be able to show that this is identity and also construct the number operator which is  $b^\dagger b$  and turns out to be please verify this but we need in the Hamiltonian  $\pi_x^2 + \pi_y^2$ .

So you can take this term to the left hand side and try to rewrite your Hamiltonian and rewritten Hamiltonian is exactly similar to what you would have seen in the harmonic oscillator with the  $b^\dagger b$  is like the number operator, the frequency  $\omega$  is  $eB/m$  which is your familiar cyclotron frequency. So once you have this Hamiltonian rewritten looking like a harmonic oscillator you can read off the spectrum as  $(n + 1/2) \hbar \omega_c + \text{free particle along } z \text{ direction}$  which is  $\hbar \omega_c$  (08:56).

The thing which we did if you recall, we worked out the position space wave function and we took  $\psi_0$  (09:05) trial function for it but if you want to work it out, you have to make a great choice okay.

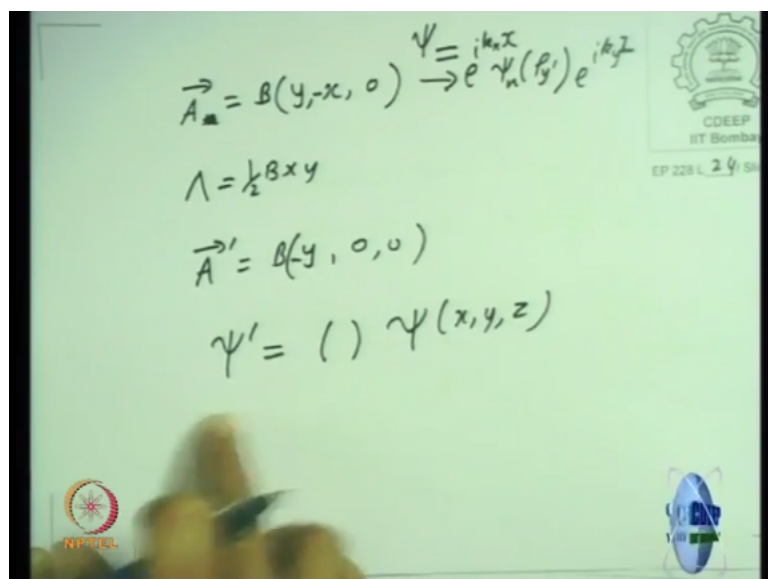

**(Refer Slide Time: 09:22)**

So just for completeness, the Hamiltonian the particle in a magnetic field Hamiltonian, suppose we take the wave function energy eigenvalue is  $E$ . By doing a gauge transformation  $A$  to  $A + \nabla\lambda$ , you could get a new Hamiltonian but this Hamiltonian is what we could call it as a canonical transformation of the original Hamiltonian because the energy spectrum remains the same, it is just that wave function will pick up an overall phase factor and no physics changes if you pick up the phase factors.

But we will see in some situations like Aharonov-Bohm effect where such phase factors will become important. If anybody is interested, can take a look at Bohm-Aharonov effect okay. So this is what we did in the class a couple of lectures ago.

**(Refer Slide Time: 10:18)**

Maybe yeah where we took a choice for A and a trial wave function but you can also see by doing a gauge transformation using the lambda gauge parameter. You could actually get a new vector potential and try to see how the wave function changes by a phase factor okay.

**(Refer Slide Time: 10:40)**

Heisenberg Equation of motion

- Please work out  $d\hat{x}_i/dt$  in Heisenberg picture:

$$\frac{d\hat{x}_i}{dt} = \frac{1}{i\hbar} [\hat{x}_i, \hat{H}] = \frac{p_i - eA_i}{m}$$

- Using this result, work out

$$m \frac{d^2\hat{x}_i}{dt^2} = m \frac{1}{i\hbar} \left[ \frac{d\hat{x}_i}{dt}, \hat{H} \right] = \text{Lorentz force } F_i$$

NPTEL CDEEP IIT BOMBAY

Lecture 21: Oscillator algebra and applications

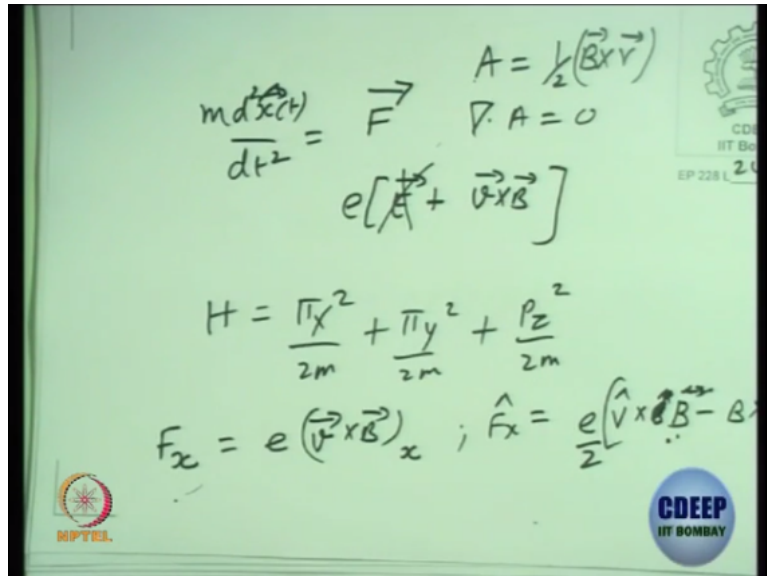

So now that we have got the energy spectrum if you recall for this Hamiltonian, I said you should get the Lorentz force, I do not know how many of you have already worked it out but if you have not recall Lorentz force theorem and that should be obtainable in the Heisenberg picture writing the Heisenberg equations of motion. So in the Heisenberg picture workout  $d\hat{x}_i/dt$  which is given by your familiar commutator of  $\hat{x}_i$  with the Hamiltonian.

So if we work it out, you will be able to see this. We would like to work out the  $m d^2\hat{x}_i/dt^2$  okay. So this is something which you need to work it out. So if  $d/dt$  of  $d\hat{x}_i/dt$  so the operator is  $d\hat{x}_i/dt$  which will show up on the next right hand side with the commutator with the Hamiltonian. So this I want you to work it out and what is your expectation. This is the force law for a particle in a magnetic field.

So this should be proportional to your Lorentz force  $F_i$  yeah. So here this is your classical force equation where  $F$  is the Lorentz force.

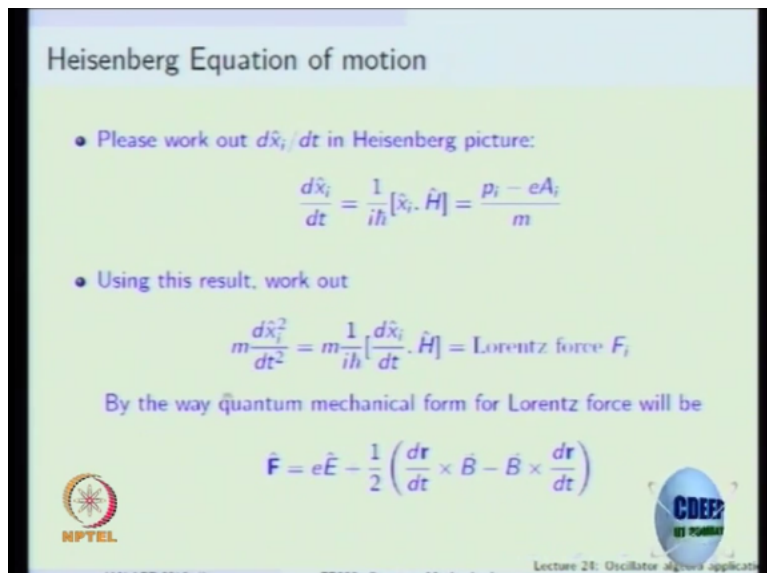

**(Refer Slide Time: 12:04)**

And let us work with the case where the electric field is zero, this is what we are doing now. If you are taking a particle in a magnetic field and this is the Hamiltonian x component of the force, I would have written it as P cross P in classical physics but if you go to quantum mechanics you have to write a Hermitian operator. In fact, when you write the Heisenberg's equation of motion for d squared xi/dt squared you will exactly get this combination V cross B-B cross V will show up there okay please check it.

**(Refer Slide Time: 12:40)**

So please check that this force the quantum mechanical force form for the Lorentz force should have the Hermitian operator which is the combination of dr/dt cross B-B cross dr/dt for the Lorentz force and we can set E to be 0 because we are working with (()) (13:03) is 0 okay. So far I have tried to show how using the harmonic oscillator algebra, trying to write

the Hamiltonian for a particle in a magnetic field in terms of the ladder operators we could get the spectrum.

And I have also tried to use the Heisenberg's equations of motion and derived for you the familiar Lorentz force.

(Refer Slide Time: 13:32)

Angular momentum algebra

- We have seen the orbital angular momentum  $\hat{L}_i$  and spin angular momentum  $\hat{S}_i$  obey the same algebra

$$[L_i, L_j] = i\hbar \epsilon_{ijk} L_k ; [S_i, S_j] = i\hbar \epsilon_{ijk} S_k ;$$

NPTEL CDEEP IIT BOMBAY

This will move on to the angular momentum algebra taking some of these data of these ladder operators and whether we can find the states for the angular momentum operators. So recall the orbital angular momentum and the spin angular momentum which we discussed last week for the Stern-Gerlach experiment.

(Refer Slide Time: 14:00)

$[L_x, L_y] = i\hbar L_z$   
 $[L^2, L_z] = 0$   
 $L^2 |l m\rangle = l(l+1)\hbar^2 |l m\rangle$   
 $L_z |l m\rangle = m\hbar |l m\rangle$   
 $L_x |l m\rangle = ?$   $[L^2, L_x] = 0$   
 $L_y |l m\rangle = ?$

NPTEL CDEEP IIT BOMBAY

So  $L_x L_y$  is  $i\hbar$  cross  $L_z$  and  $L \cdot L$  commutes with all the components, for conventions we are going to take it with respect to  $L_z$  and we write it to be a simultaneous eigenstate of  $L_z$  and  $L \cdot L$  and these are the eigenvalue equations with eigenvalues which we have seen when we discussed this hydrogen atom and the questions we should ask is how  $L_x$  operates on  $l_m$  and similarly how  $L_y$  operates on  $l_m$  okay. What do we get are the questions which you would like to know?

**(Refer Slide Time: 14:35)**

**Angular momentum algebra**

- We have seen the orbital angular momentum  $\hat{L}_i$  and spin angular momentum  $\hat{S}_i$  obey the same algebra
 
$$[L_i, L_j] = i\hbar \epsilon_{ijk} L_k \quad ; \quad [S_i, S_j] = i\hbar \epsilon_{ijk} S_k \quad ;$$

$$[L_i, S_j] = 0 \quad ;$$

$$[L \cdot L, L_i] = [S \cdot S, S_i] = 0$$
- We will denote angular momentum as  $J_i$  from now on
 
$$[J_i, J_j] = i\hbar \epsilon_{ijk} J_k \quad ; \quad [J \cdot J, J_i] = 0$$
- Motivated by ladder operators in harmonic oscillator, we will write non-hermitean operators
 
$$J_{\pm} = J_x \pm iJ_y$$

Logos for NPTEL and CDEEP are visible at the bottom of the slide.

So we have seen orbital angular momentum and spin angular momentum. They obey the same algebra. This is what I tried to motivate you from Stern-Gerlach experiment. It exactly behaves the algebra of the spin operator should be exactly similar to what we have plus they are in two different spaces. They have to be 0 and we have this condition which is the simultaneous eigenstate of  $L^2$  and  $L_z$ .

We are checking the  $i$  to be the  $z$  component for convenience and universally following whatever books are doing and similarly you can have it to be a simultaneous eigenstates of  $S^2$  and this is it. (()) (15:18) trying to talk whether we are talking about orbital angular momentum or spin angular momentum. We will compactly write angular momentum by a symbol  $J$  and the  $J$  will satisfy the same property.

And we will write eigenstates of  $J^2$  and  $J_z$  to be the simultaneous eigenstates. So we have done this all ladder operators. The ladder operators are not Hermitian operators. You cannot experimentally observe them.  $A$  is not equal to  $A^\dagger$  that is why you have two

ladder operators; they are not Hermitian. Similarly, we would like to do a ladder operator here using these angular momentum  $J_x$ ,  $J_y$  and  $J_z$  okay.

Motivated by these harmonic oscillator ladder operators let us write  $J_+$  as  $J_1 + iJ_2$ . I am using 1 2 and 3 as x y and z okay and  $J_-$  as  $J_1 - iJ_2$ . It is similar to the angular momentum operators which I am writing  $J_+$  and  $J_-$  are looking similar to the way we wrote non-Hermitian operators in the oscillator algebra. What is the next thing? I had this  $J_x J_y$  to be  $i\hbar$  cross  $J_z$ . I would like to write the commutator of  $J_+$  with  $J_-$ ,  $J_+$  with  $J_z$  and  $J_-$  with  $J_z$ . So that I can try to play around and find how to go about this problem.

**(Refer Slide Time: 17:08)**

• Write down the algebra using these ladder operators with  $J_3$

$$\begin{aligned} [J_+, J_-] &= 2\hbar J_3 ; \\ [J_+, J_3] &= -\hbar J_+ ; \\ [J_-, J_3] &= \hbar J_- . \end{aligned}$$

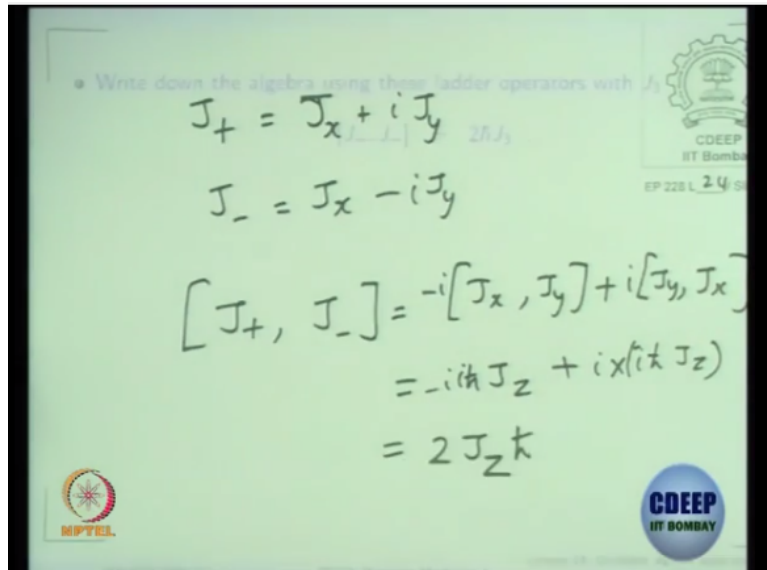

NPTEL logo: A circular logo with a star-like pattern and the text 'NPTEL' below it.

COEP BY SOMBAJ logo: A blue circular logo with the text 'COEP BY SOMBAJ' inside.

Footer text: 'Lecture 21: Oscillator algebra application'.

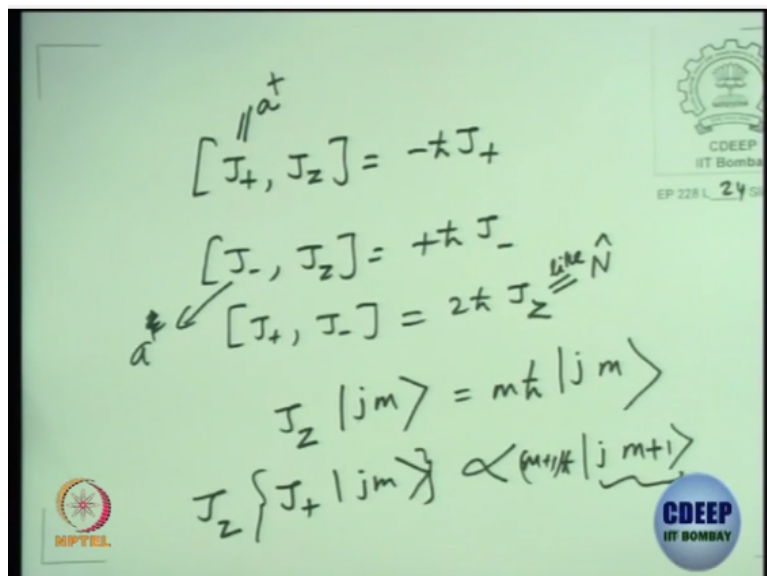

So write down the algebra using these ladder operators which is  $J_+$  or  $-$  with  $J_3$ . What will this be? Can you work it out?

**(Refer Slide Time: 17:15)**

What is this? The negative side right. Is that right? What is this answer turning out to be? So it is twice  $\hbar J_z$  and do the  $J_+$  with  $J_z$  excellent. So it is  $+\hbar$  cross  $J_+$  or  $-\hbar$  cross. So the same algebra of  $J_x J_y J_z$  which we wrote, I am trying to rewrite yeah  $J_+$  with  $J_-$  what it is which is like your  $a$  and  $a^\dagger$ , something wrong – okay. Both of them are – yeah, sorry. The third one is  $+$  and second one is  $-$  okay I will correct it please try to.

**(Refer Slide Time: 18:48)**

So  $J_+$  with  $J_z$  or  $J_z$  is  $-\hbar$  cross  $J_+$  and  $J_-$  with  $J_z$  is  $+\hbar$  cross  $J_-$  and  $J_+$  with  $J_-$  is twice  $\hbar$  cross  $J_z$ . Now let us compare with the harmonic oscillator, kind of said that the states are eigenstates of  $J_z$  from the hydrogen atom experience right. So this is similar to your number operator  $(\hat{N})$  (19:28) not exactly okay. It is like  $J_z$  operator is like number operator. If I write my state as  $j m$  with  $J_z$  operator, it gives you  $m \hbar$  cross  $j m$ .

We have one more because we know  $J \cdot J$  it is an eigenstate of  $J \cdot J$  that is why I put this additional index. Otherwise, I could have just work with  $m$  okay. The maximal compatible set for an angular momentum algebra is simultaneous eigenstate of  $J \cdot J$  and  $J_z$  that is why I have two integers. So  $J_z$  is like your number operator in harmonic oscillator. It is an eigenstate with eigenvalue  $m\hbar$ .

Then, what does it tell us?  $J_+$  and  $J_-$  are like your, I do not know one of them will be a and the other one will be probably a dagger or the other way around okay. So this algebra will actually tell you what happens to  $J_+$  on  $|j, m\rangle$ . If you remember when we did the oscillator, we tried to say that  $a$  on  $n$ , how did we argue  $a$  on  $n$ ?  $a$  on  $n$  went to  $n-1$  or  $n+1$  so I think it is like a dagger and this is like  $a$ .

Rewrite it that way, then this will become a  $+$  sign, that will become a  $-$  sign. Then, that will be like the  $a$  dagger and  $a$  excellent. This has to make you think also and do it. So use this algebra and try to figure out that it is like a ladder operator. It is not an eigenstate but this one will be an eigenstate right. This will be an eigenstate of  $J_z$  with eigenvalue  $(m+1)\hbar$  that is why we wrote the state as use this algebra.

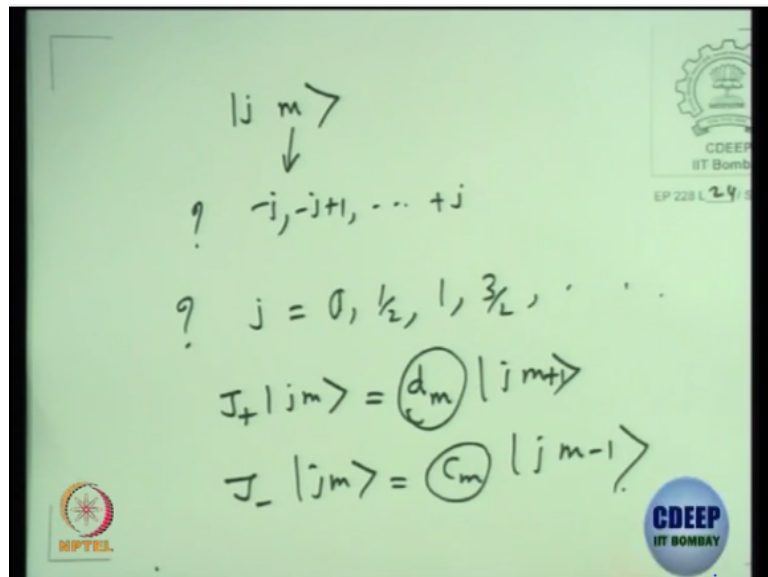

Similarly, the next one to figure out that it will be a lowering operator. You see the power of algebra now. How we are exploiting the power of algebra. What is left? You have to determine these coefficients that is right. So that is from the hydrogen atom data but we will do it independently now and show that how the restrictions are that is all. So those things will come to, those things are not visible here.

I am just saying it is like. If it is exactly harmonic oscillators, then nothing more to do. As he is pointing it out, there is no information that  $m$  goes from  $-j$  to  $+j$  and you cannot have raising operator going to infinity like the way you did it in harmonic oscillator okay. So we need to fix those things, will come to fixing that. I am just saying that you can if  $|j, m\rangle$  is an eigenstate given to you which is a simultaneous eigenstate of  $J^2$  and  $J_z$ , I can actually get the trend how the  $J_+$  and  $J_-$  operates on it from this algebra.

That is all I said but this coefficient of proportionality has to be fixed and also these issues that  $m$  should go from  $-J$  to  $+J$  also  $J$  could be integers or half-odd-integers. All these things

are not fixed right now. I am just using hydrogen atom data and just doing this but we will now do explicitly to figure out all these informations.

**(Refer Slide Time: 23:14)**

So I need to figure out that  $j$  and  $m$ ,  $m$  goes from  $-j, -j+1$ , till  $+j$ . This has to be figured out. You have to also figure out whether  $J$  could be  $0, 1/2, 1, 3/2$  you know these are the possibilities has to be. In the orbital angular momentum in hydrogen atom, it was only integers. Now we have to naturally see whether we can get half-odd-integers. This is also to be figured out.

What else I need to also figure out  $j, m$  as  $d, m$  on  $j, m$ , what is this  $d, m$ ,  $J_+$  on  $j, m$  is some  $C, m$  on  $j, m-1$ . We need to figure this out also where some of these things have not been fixed as of now. So we need to fix this. Is this clear? The problem clear, how do we do this? Yeah, so there is another nice trick which we are going to do. This is what is the Schwinger method. Let us do that just as okay.

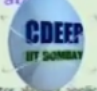

**(Refer Slide Time: 24:19)**

- Write down the algebra using these ladder operators with  $J_3$ 

$$[J_+, J_-] = 2\hbar J_3 ;$$

$$[J_+, J_3] = \hbar J_- ;$$

$$[J_-, J_3] = \hbar J_+ .$$
- The maximal compatible set of operators from angular momentum algebra is  $J^2, J_3$  and we can write simultaneous eigenstates as  $|jm\rangle$   
 $J^2|jm\rangle = j(j+1)\hbar^2|jm\rangle ; J_3|jm\rangle = m\hbar|jm\rangle$
- We will show that  $J_+$  is raising operator and  $J_-$  is the lowering operator  
 $J_+|jm\rangle \propto |j, m+1\rangle ; J_-|jm\rangle \propto |j, m-1\rangle$   
 Need to determine the proportionality constant using the above algebra.

LECTURE 21: Oscillator algebra applications

So this is things I have said except for this negative sign which is here. So all the other things are fine and we can write simultaneous eigenstates  $jm$  which is an eigenstate of  $J^2$  and  $J_3$  and we will show that  $J_+$  is a raising operator and  $J_-$  is a lowering operator. This also you can see from this algebra is what I was trying to tell you. Only proportionality constant has to be figured out using this above algebra.

Not only that as he has already pointed out that we need to figure out  $m$  takes values from  $-J$  to  $+J$ . You have to also figure out that  $J$  could be integers, could be half-odd-integers. All these possibilities because if you lose Stern-Gerlach  $J$  is actually half. If you do orbital angular momentum,  $J$  is actually integers. So all possibilities are allowed has to be figured out. We have not still done that okay. So for that we use this Schwinger oscillator method.

**(Refer Slide Time: 25:24)**

### Schwinger oscillator method

- Construction of angular momentum algebra using ladder operators of two independent oscillators:  $a, a^\dagger, b, b^\dagger$   
 $[a, a^\dagger] = [b, b^\dagger] = 1 ;$   
 rest of the commutators are zero like  $[a, b] = [a, b^\dagger] = 0$
- Representation for  $J_\pm, J_3$  is as follows
 
$$J_+ = \hbar a^\dagger b$$

$$J_- = \hbar a b^\dagger$$
- Work out  $[J_+, J_-] = 2J_3$  to determine  $J_3$ 

$$J_3 = \frac{\hbar}{2}(a^\dagger a - b^\dagger b) = \frac{\hbar}{2}(N_a - N_b)$$
- What is the form of  $J^2$  in terms of the two harmonic oscillator ladder operators?
 
$$J^2 = \hbar^2 \frac{(N_a + N_b)}{2} \left( \frac{N_a + N_b}{2} - 1 \right)$$

LECTURE 21: Oscillator algebra applications

What is the theme? Theme is to generate the angular momentum algebra using two independent oscillator algebras. There are two independent oscillators for the system, one with  $a$  and  $a^\dagger$ , another one with  $b$  and  $b^\dagger$ . Do not confuse this  $B$  with what I wrote with  $\pi x^+$  so this is just a two independent oscillators. You can call  $a_1$   $a_1^\dagger$   $a_2$   $a_2^\dagger$  if you want but you can as two independent oscillators.

So we are going to write address. This is what is called representation right. You can represent the angular momentum ladder operators  $J_+$   $J_-$  and  $J_z$  or  $J_3$  as follows. Let us take two ladder operators with one of them as raising and another one does lowering. By independent, I mean that between  $A$  and  $B$ , the commutator is always 0,  $a$  and  $a^\dagger$  will be harmonic oscillator algebra,  $b$  with  $b^\dagger$  is harmonic oscillator algebra.

Between  $a$  and  $b$  or  $a$  and  $b^\dagger$  or  $a^\dagger$  and  $b$  you know  $a^\dagger$  with  $b^\dagger$  they are all 0. This is what I mean by rest of the commutators are 0. They do not talk to each other. They are independent. Using two independent harmonic oscillator, we could write a product of two ladder operators. If you note here, one ladder operator is like raising, the other one is like lowering.

It is just combination which we take; the  $J_-$  is Hermitian conjugate of this. You can take the dagger of this and you should get the  $J_-$ . Order is really does not matter because whether I put first  $b$  and next  $a$  or  $a$  and  $b$  does not matter because they commute. I can work with this. So now to find what is  $J_3$  substitute these two here and determine what you get for  $J_3$ . I will leave it to you to do this. Please try this out.  $J_3$  should be a function of again involving the 4 ladder operators okay.

Please try this out and interestingly if you work this out, you will find that you get it to be a difference between the number operators. Please work this out okay. Similarly, work out what is  $J \cdot J$ . Please work out what is  $J \cdot J$ .  $N_a$  is the number operator for the harmonic oscillator with ladder operators  $a$  and  $a^\dagger$  so  $N_a$  is nothing but it is  $a^\dagger a$ .  $N_b$  is the harmonic oscillator with ladder operators  $b$  and  $b^\dagger$ .

I am not bothered about the frequencies of the two oscillators. For me I am more interested in constructing the angular momentum algebra in terms of the two harmonic oscillator ladder

operators. Is it okay? So please work this out  $J \cdot J$  and tell me what you get okay. Please  
very whether you get this. Let me stop here today.
