Module-03
Lecture-38
Quantum Langevin Noise

Hello, welcome to lecture 28 of the Course, this is lecture 7 of module 3. In this lecture we will discuss the classical counterpart of Langevin noise that is quantum Langevin noise and finally we will begin our discussion on the effect of quantum noise on an optical mode in a Fabry-Perot cavity. As Fabry-Perot cavity is the backbone of a cavity of the mechanical system. So, let us begin.

(Refer Slide Time: 01:01)

Last class

$$H = \underbrace{\frac{p^2}{2m} + \frac{1}{2} m \omega_m^2 z^2}_H + \underbrace{\sum_{i=1}^N \left(\frac{p_i^2}{2m_i} + \frac{1}{2} m_i \omega_i^2 z_i^2 \right)}_{H_B} - \underbrace{z \sum_{i=1}^N c_i q_i}_{H_{SB}} + z^2 \sum_{i=1}^N \frac{c_i^2}{2m_i \omega_i^2}$$

Diagram: A central box labeled "System" is connected to a larger box labeled "Bath". The bath contains several smaller circles representing oscillators, each with a coordinate q_i and a coupling constant c_i . The system coordinate is z .

$$m \ddot{z} + m \omega_m^2 z + m \int_{-\infty}^t dt' \gamma(t-t') \dot{z}(t') = \xi(t)$$

In the last class we continued our discussion on modeling a realistic situation regarding the interaction of the system harmonic oscillator with the surrounding. The surrounding was modelled as a collection of independent harmonic oscillator N harmonic oscillator each having different coupling coefficient or coupling constant.

(Refer Slide Time: 01:27)

$$\begin{aligned}
 & \bullet \quad m \ddot{q} + m \omega_m^2 q + m \int_0^t dt' \gamma(t-t') \dot{q}(t') = \underline{\underline{\xi(t)}} \\
 & \xi(t) = \sum_{i=1}^N c_i \left\{ \left[q_i(0) - \frac{c_i}{m_i \omega_i^2} q(0) \right] \cos \omega_i t + \frac{p_i(0)}{m_i \omega_i} \sin \omega_i t \right\} \\
 & \bullet \quad \gamma(t) = \frac{1}{m} \sum_{i=1}^N \frac{c_i^2}{m_i \omega_i^2} \cos \omega_i t \quad (\text{Memory Function})
 \end{aligned}$$

And our analysis ultimately led to an equation of motion for the damped harmonic oscillator and we got a memory function defined as this quantity gamma of t and on the right-hand side of the equation we get a parameter called Xi of t and this is so-called Langevin noise.

(Refer Slide Time: 01:54)

→ The memory function is simplified by defining a function J(ω), the bath spectral density,

$$J(\omega) = \pi \sum_{i=1}^N \frac{c_i^2}{2m_i \omega_i} \delta(\omega - \omega_i)$$

And this memory function was simplified defining a function called bath spectral density denoted by the quantity J of omega.

(Refer Slide Time: 02:05)

$$\gamma(t) = \frac{2}{m} \int_0^\infty \frac{d\omega}{\pi} \frac{J(\omega)}{\omega} \cos \omega t$$

For many practical cases:

$$J(\omega) = m\gamma_m \omega \rightarrow \text{Ohmic damping}$$

And using this, this memory function can be written in this particular form and in fact for many practical cases this bath spectral parameter can be taken as a mass into the mechanical damping γ into ω . This is known as the Ohmic damping.

(Refer Slide Time: 02:29)

\Rightarrow Ohmic model results that does not depend on any earlier time $t' < t$

\Downarrow

The bath has no memory \rightarrow Markovian

And we obtained:

$$m\ddot{z} + m\gamma_m \dot{z} + m\omega_m^2 z = \underline{\underline{\xi(t)}}$$

Bath correlation function

$$\langle \xi(t) \rangle$$

So, under Ohmic damping this memory function will take this form. In fact, Ohmic model results in a damping that does not depend on the previous history of the bath, it does not depend on any earlier time and therefore this process is known as the Markovian process and we obtain these equations here. Now on the right-hand side of this equation we have this Langevin noise and this is actually also called thermal force.

And this clearly shows that unlike the other case when it is 0 in that case transfer of energy can take place from the system harmonic oscillator to the surrounding but not from the

surrounding to the system oscillator. So, here presence of this Langevin noise says that both process is possible. That means transport of energy from the system oscillator to the surrounding and back from the surrounding to the system oscillator and thereby the system will come into a thermal equilibrium.

(Refer Slide Time: 03:43)

Bath correlation function

- $\langle \xi(t) \rangle$
- $\langle \xi(t) \xi(t') \rangle$: autocorrelation

System-bath coupling c_i is weak:

$$\xi(t) = \sum_{i=1}^N c_i \left[q_i(0) \cos \omega_i t + \frac{p_i(0)}{m_i \omega_i} \sin \omega_i t \right]$$

Then we went on to calculate the bath correlation function and this ξ of t as it is the Langevin noise, and it is related to the bath and we try to calculate the first moment that is average of the Langevin noise and its auto correlation function that is the second moment.

(Refer Slide Time: 04:10)

- $\langle \xi(t) \rangle = 0$
- $\langle \xi(t) \xi(t') \rangle = \sum_{i,j} c_i c_j \left[\langle q_i(0) q_j(0) \rangle \cos \omega_i t \cos \omega_j t' + \frac{\langle p_i(0) p_j(0) \rangle}{m_i m_j \omega_i \omega_j} \sin \omega_i t \sin \omega_j t' + \frac{\langle q_i(0) p_j(0) \rangle}{m_j \omega_j} \cos \omega_i t \sin \omega_j t' + \frac{\langle q_j(0) p_i(0) \rangle}{m_i \omega_i} \sin \omega_i t \cos \omega_j t' \right]$
- $\langle q_i(0) q_j(0) \rangle = \frac{k_B T}{m_i \omega_i^2} \delta_{ij}$
- $\langle p_i(0) p_j(0) \rangle = m_i k_B T \delta_{ij}$

So, here what we assume that the system bath coupling is weak and then this Langevin noise expression become a little bit simplified and our calculation led us to the fact that necessarily

the average value of the Langevin noise is 0. And the bath correlation function we calculated and in the process, we learned how to calculate the average value of various quantities.

(Refer Slide Time: 04:37)

$\langle q_i(0) q_j(0) \rangle = \frac{\hbar}{m_i \omega_i^2} \delta_{ij}$
 $\langle p_i(0) p_j(0) \rangle = m_i k_B T \delta_{ij}$
 $\langle q_i(0) p_j(0) \rangle = \langle p_j(0) q_i(0) \rangle = 0$

Thus,

$\langle \dot{x}(t) \dot{x}(t') \rangle = 2 m \gamma_m k_B T \delta(t-t')$

- # Each interaction of the bath with the system oscillator through Langevin noise \dot{x} is correlated **ONLY** to itself and to **NO** other interactions
- # Strength of the fluctuations varies directly with mechanical damping γ_m

And it turns out that this second moment or the auto correlation function Langevin noise is an expression like this and physically it says that the interaction of the bath with the system oscillator via the Langevin noise is correlated only to itself and not to any other interaction and also the strength of the fluctuation varies directly with the mechanical damping parameter γ_m which is again related to the so-called fluctuation dissipation theorem.

(Refer Slide Time: 05:14)

Wiener-Khinchin theorem

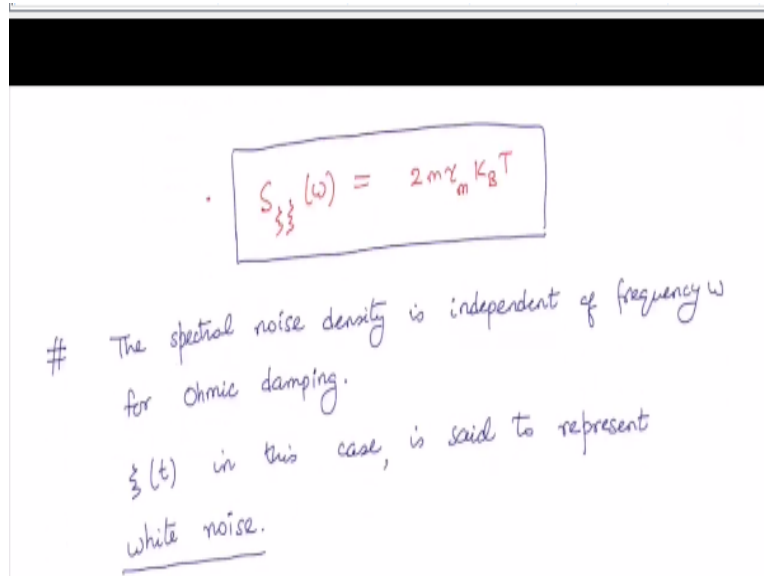

$S_{xx}(\omega) = \int_{-\infty}^{\infty} dt e^{i\omega t} \langle x(t) x(0) \rangle$
 $S_{\dot{x}\dot{x}}(\omega) = \int_{-\infty}^{\infty} dt e^{i\omega t} \langle \dot{x}(t) \dot{x}(0) \rangle$

↑
Spectral noise density

And we went to recall the Wiener-Khinchin theorem which we discussed in the context of movable mirror in an earlier class which basically says that the noise spectrum is nothing but the Fourier transform of the correlator and in analogy to this we have written down the noise

spectrum for the bath and which is known as the spectral noise density and that is the Fourier transform of the second moment of the Langevin noise.

(Refer Slide Time: 05:53)

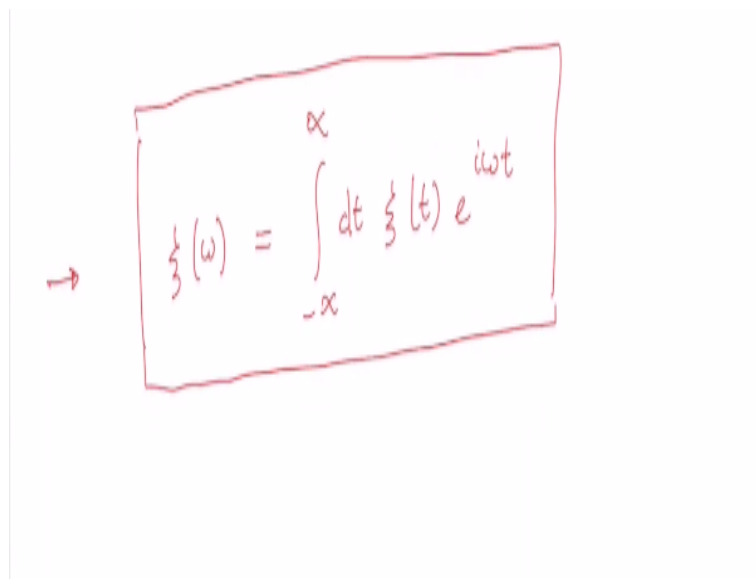

$$S_{\xi\xi}(\omega) = 2m\gamma_m k_B T$$

The spectral noise density is independent of frequency ω for Ohmic damping.
 $\xi(t)$ in this case, is said to represent white noise.

And we worked out that this for Ohmic damping this turns out to be a very simple expression and it is independent of the frequency for Ohmic damping and that is the reason that in the case of Ohmic damping the Langevin noise is said to represent the so-called white noise.

(Refer Slide Time: 06:12)

$$\xi(\omega) = \int_{-\infty}^{\infty} dt \xi(t) e^{i\omega t}$$

And this Langevin noise can be expressed in the frequency domain also just by taking the Fourier transformation.

(Refer Slide Time: 06:23)

Quantum Regime :

Assume the bath to be a collection of N independent Quantum Harmonic Oscillators at temperature T .

$$\langle \hat{A} \rangle = \text{Tr}(\rho \hat{A})$$

$$\rho_{th} = \sum_{n=0}^{\infty} P_n |n\rangle \langle n|$$

$$\text{Here, } P_n = \frac{e^{-E_n/k_B T}}{\sum_{n=0}^{\infty} e^{-E_n/k_B T}}$$

$$E_n = \left(n + \frac{1}{2}\right) \hbar \omega \approx n \hbar \omega$$

Then we started discussing the quantum regime. To discuss quantum regime, we now have to calculate the expectation value of various parameters, and because we are considering a collection of N independent harmonic oscillator at some temperature T . So, we written down the density operator for the system and that will be required because we know that when we take the average of any quantum optomechanical operator expectation value is given by the trace of the rho density operator into the operator. So, this has to be calculated so we worked out the thermal density operator for these thermal oscillators in the thermal state.

(Refer Slide Time: 07:14)

$$\begin{aligned} \text{Tr}(\rho_{th}) &= \sum_{k=0}^{\infty} \sum_{n=0}^{\infty} P_n \langle k|n\rangle \langle n|k\rangle \\ &\quad \parallel \\ &\quad \delta_{nk} \\ &= \sum_{n=0}^{\infty} P_n \\ &= 1 \end{aligned}$$

Average phonon number:

$$\begin{aligned} \langle \hat{b}^\dagger \hat{b} \rangle &= \text{Tr} \left[\rho_{\text{th}} \hat{b}^\dagger \hat{b} \right] \\ &= \sum_{l=0}^{\infty} \langle l | \hat{b}^\dagger \hat{b} \sum_{n=0}^{\infty} P_n |n\rangle \langle n|l\rangle \\ &\quad \parallel \delta_{nl} \\ &= \sum_{n=0}^{\infty} n P_n \end{aligned}$$

$$\langle \hat{b}^\dagger \hat{b} \rangle = \frac{\sum_{n=0}^{\infty} n e^{-E_n/k_B T}}{\sum_{n=0}^{\infty} e^{-E_n/k_B T}}$$

And we calculated the average phonon number, because these are thermal mechanical modelling, it is a oscillator and in the thermal environment the quantum is termed as phonon there and we use the symbol b to represent this phononic oscillator.

(Refer Slide Time: 07:38)

$$\begin{aligned} \Rightarrow \langle \hat{b}^\dagger \hat{b} \rangle &= \frac{\sum_{n=0}^{\infty} n e^{-E_n/k_B T}}{\sum_{n=0}^{\infty} e^{-E_n/k_B T}} \\ &= \frac{\sum_{n=0}^{\infty} n e^{-n\hbar\omega_m/k_B T}}{\sum_{n=0}^{\infty} e^{-n\hbar\omega_m/k_B T}} \\ \sum_{n=0}^{\infty} e^{-ns} &= 1 + e^{-s} + e^{-2s} + \dots = \frac{1}{1 - e^{-s}} \\ \sum_{n=0}^{\infty} n e^{-ns} &= -\frac{d}{ds} \sum_{n=0}^{\infty} e^{-ns} = -\frac{d}{ds} \left(\frac{1}{1 - e^{-s}} \right) \end{aligned}$$

$$\begin{aligned}
 n=0 & \\
 &= \frac{e^{-s}}{(1-e^{-s})^2} \\
 \langle \hat{b}^\dagger \hat{b} \rangle &= \frac{e^{-\hbar\omega_m/k_B T}}{(1 - e^{-\hbar\omega_m/k_B T})} \\
 &= \frac{1}{e^{\hbar\omega_m/k_B T} - 1} = n(\omega_m)
 \end{aligned}$$

• Position - position correlation for an ensemble of N-harmonic oscillators

And we calculated the average value of phonon number which is the usual this is the familiar expression we obtain.

(Refer Slide Time: 07:49)

$$\begin{aligned}
 & e^{-\beta} \\
 \bullet & \text{ Position - position correlation for an ensemble of N-harmonic oscillators } \\
 & \langle q_i q_j \rangle \\
 \rho_{th} &= \left(\sum_{n_1=0}^{\infty} P_{n_1} |n_1\rangle \langle n_1| \right) \left(\sum_{n_2=0}^{\infty} P_{n_2} |n_2\rangle \langle n_2| \right) \\
 & \dots \left(\sum_{n_N=0}^{\infty} P_{n_N} |n_N\rangle \langle n_N| \right) \\
 \rho_{th} &\equiv \sum \prod P_{n_k} | \{n_k\} \rangle \langle \{n_k\} |
 \end{aligned}$$

where $\{n_k\} = (n_1, n_2, \dots, n_N)$
 $|\{n_k\}\rangle = |n_1\rangle |n_2\rangle \dots |n_N\rangle$

$$\langle q_i, q_j \rangle = \text{Tr} (\rho_{th} q_i q_j)$$

$$= \sum_{\{n_p\}} \langle \{n_p\} | \rho_{th} q_i q_j | \{n_p\} \rangle$$

$$= \sum_{\{n_p\}} \langle \{n_p\} | \sum_{\{n_k\}} \prod_k P_{n_k} | \{n_k\} \rangle \langle \{n_k\} | q_i q_j | \{n_p\} \rangle$$

$$= \sum_{\{n_k\}} \prod_k P_{n_k} \langle \{n_k\} | q_i q_j | \{n_k\} \rangle$$

$$\langle q_i, q_j \rangle = \sum_{\{n_k\}} \prod_k P_{n_k} \langle \{n_k\} | q_i q_j | \{n_k\} \rangle$$

Note $\{n_k\} = (n_1, n_2, \dots, n_N)$
 $|\{n_k\}\rangle = |n_1\rangle |n_2\rangle |n_3\rangle \dots |n_N\rangle$

And then we try to calculate the position-position correlation for an ensemble of N harmonic oscillators and we finally obtain this particular expression. Now we are going to build up our next analysis from here only thing let me remind you that you should understand this notation here it is bracketed n k represents this one. So, it is a collection of all n 1, n 2 up to n N number of items we have there and this ket represents the direct product of various number state corresponding to the oscillators. Let us now write the position operators this q i, q j. These are operators.

(Refer Slide Time: 08:38)

$$q_i = q_{i0} (b_i + b_i^\dagger), \quad q_{i0} = \sqrt{\frac{\hbar}{2m_i\omega_i}}$$

$$q_j = q_{j0} (b_j + b_j^\dagger)$$

$$q_{j0} = \sqrt{\frac{\hbar}{2m_j\omega_j}}$$

$$\left[\begin{array}{l} x = x_{zpf} (a + a^\dagger) \\ x_{zpf} = \sqrt{\frac{\hbar}{2m\omega}} \end{array} \right]$$

Let me write q_i is equal to I am not using this operator sign but you please understand that I am not talking about operator because now we are in the quantum regime. So, $q_i = q_{i0} (b_i + b_i^\dagger)$ into $b_i + b_i^\dagger$. This is the position operator for the i th oscillator and here q_{i0} is equal to this is the zero-point fluctuation, this is \hbar cross divided by twice $m_i \omega_i$, m_i is the mass of the oscillator i th oscillator and ω_i is the corresponding resonance frequency.

Now by the way please recall that we have utilized a similar thing earlier when we have this displacement operator x . In this we wrote earlier in the context of when we discuss about harmonic oscillator, this is x zero-point fluctuation and we there we used $a + a^\dagger$. Now x zero point this fluctuation was defined as \hbar cross divided by twice $m \omega$. The same thing here we are doing it and we can then also write for q_j . For q_j we have q_{j0} for the j th oscillator. $b_j + b_j^\dagger$ and here $q_{j0} = \hbar$ cross divided by twice $m_j \omega_j$. Now we have to calculate this particular quantity.

(Refer Slide Time: 10:32)

$$\begin{aligned}
& \langle \{n_k\} | a_i a_j | \{n_k\} \rangle \\
&= a_{i0} a_{j0} \langle n_1 n_2 \dots n_N | b_i^\dagger b_j + b_i b_j^\dagger + \underbrace{b_i^\dagger b_j^\dagger + b_i b_j}_{n_1 n_2 \dots n_N} | \rangle \\
&= a_{i0} a_{j0} \langle n_1 n_2 \dots n_i, \dots n_N | b_i^\dagger b_j + b_i b_j^\dagger | n_1 n_2 \dots n_j, \dots n_N \rangle
\end{aligned}$$

So, let us do that, first of all let us calculate this bracketed bra of this number states q_i, q_j and this ket basically we are calculating the scalar product for this product of this operators q_i, q_j . Now if I put q_i, q_j I have q_{i0}, q_{j0} and this is actually I can write it as n_1, n_2, \dots, n_N , these are the direct products up to n_N in short hand notation q_i, q_j if I break it up so I will get 4 terms, so those would be $b_i^\dagger b_j + b_i b_j^\dagger + b_i^\dagger b_j^\dagger + b_i b_j$ and we will have b_i, b_j .

And then on the other side you will have n_1, n_2 up to N number of oscillators. So, we will have the corresponding quantity for that and you will see that the contribution from these 2 terms, this term as well as this term is obviously going to be 0. Just recall to understand it we can calculate say $n b b$ or $n b^\dagger b^\dagger$, you can do that also. Then here you will get it as your simple calculation will give you it as $n - 1$ into $n - 2$ and you will have here $n - 2$ and these are orthogonal.

So, this would be 0, so these 2 contributions would not be there because of these 2 terms. So, I will simply have $q_{i0}, q_{j0}, n_1, n_2, \dots, n_N$ and here you will have $b_i^\dagger b_j + b_i b_j^\dagger$ and the other side you will have say n_1, n_2 let me take it. So, this anyway you have understood. This one let us say I have n_j up to n_N .

(Refer Slide Time: 13:09)

$$\begin{aligned}
&= a_{i0} a_{j0} \left[\langle \underline{n_1, n_2, \dots, (n_i-1), \dots, n_N} | \sqrt{n_i} \sqrt{n_j} | \underline{n_1, n_2, \dots, (n_i-1), \dots, n_N} \rangle \right. \\
&\quad \left. + \langle \underline{n_1, n_2, \dots, (n_i+1), \dots, n_N} | \sqrt{n_i+1} \sqrt{n_j+1} | \underline{n_1, n_2, \dots, (n_i+1), \dots, n_N} \rangle \right] \\
&= a_{i0} a_{j0} \left[\sqrt{n_i n_j} + \sqrt{(n_i+1)(n_j+1)} \right] \delta_{ij}
\end{aligned}$$

So, now let us proceed further. So, let me we calculate the term by term. So, I have $a_{i0} a_{j0}$, I have here n_1, n_2 . So, here let me first consider this particular term, so $b_i^\dagger b_j$, so b_i^\dagger when it this operator operates on the bra n_i here it will operate on only the i th oscillator. So, it would become because it is b_i^\dagger operating on this, this would become $n_i - 1$ and then you will have up to n_N .

And this will give you square root of n_i similarly when b_j operates on n_j you know you will get n_j square root of n_j and here you will have n_1, n_2 and so on up to say it will n_j would become $n_j - 1$ and you will have n_N . So, this is what you will get from the first term. Now let us consider this term and in the similar way here you will see that this would become n_1, n_2 and this i th operator b_i annihilation operator when it operate this is you will get it as n_i would become $n_i + 1$ and you will have n_N here.

And this would become square root of $n_i + 1$. Similarly, now b_j when it operates on n_j it would become square root of $n_j + 1$ and in this side you will have n_1, n_2 and you will have it as $n_j + 1$ and n_N . So, therefore I can write the whole thing as $a_{i0} a_{j0}$ square root of $n_i n_j$ + square root of $n_i + 1, n_j + 1$, you will have $n_i + 1$ and $n_j + 1$ and then I will write it as δ_{ij} because all the other terms will not contribute.

As you see this one for example $n_i - 1$ and $n_j - 1$ they would become orthonormal it will get normalized provided $i = j$, if i is not equal to j then they will vanish, because scalar product with n_1 because this is just a number n_1 and n_1 will give you 1, n_2 and n_2 will give you one scalar product but $n_i - 1$ and $n_j - 1$ will give you one provided $i = j$. Similar is the logic

for this particular second term also. So, therefore we will end up with this particular expression.

(Refer Slide Time: 16:36)

$$\langle \{n_k\} | a_i a_j | \{n_k\} \rangle = a_{i0} a_{j0} \left[\sqrt{n_i n_j} + \sqrt{(n_i + 1)(n_j + 1)} \right] \delta_{ij}$$

$$\langle a_i a_j \rangle = \sum_{\{n_k\}} \prod_k P_{n_k} a_{i0} a_{j0} \left[\sqrt{n_i n_j} + \sqrt{(n_i + 1)(n_j + 1)} \right] \delta_{ij}$$

So, therefore we have evaluated let me write it again here what we got is we have evaluated this particular quantity and we have q_i, q_j scalar product we have worked out and this is we got $q_{i0} q_{j0}$ square root of $n_i n_j +$ square root of $n_i + 1$ into $n_j + 1$ delta ij . Now let us proceed further ultimately, we have to work out the expectation value of this product of these 2 operators and this is equal to we have summation.

So, let me show you the expression once again here. So, this we have to have let me write here again we have summation over all this n_k 's and this is product and $P_{n_k} q_{i0}, q_{j0}$ this already we worked out. So, just let me copy from here this same term we are having here let me put it, let me do it, let me write here. So, $q_{i0} q_{j0}$ plus square root of $n_i n_j +$ square root of $n_i + 1 n_j + 1$ and delta ij .

(Refer Slide Time: 18:22)

$$\begin{aligned}
 \langle a_i a_j \rangle &= \sum_{\{n_k\}} \prod_k p_{n_k} e_{i0} e_{j0} [\sqrt{n_i n_j} + \sqrt{(n_i+1)(n_j+1)}] \delta_{ij} \\
 &= \left(\sum_{\{n_k \neq n_i\}} \prod_{k \neq i} p_{n_k} \right) \sum_{n_i} p_{n_i} e_{i0} e_{j0} [\sqrt{n_i n_j} + \sqrt{(n_i+1)(n_j+1)}] \delta_{ij} \\
 &\stackrel{\parallel 1}{=} \sum_{n_i} p_{n_i} e_{i0} e_{j0} [\sqrt{n_i n_j} + \sqrt{(n_i+1)(n_j+1)}] \delta_{ij}
 \end{aligned}$$

Now let us do one thing. Let us look at separated terms where k is not equal to i , so we will separate it terms like this, say when n_k is not equal to n_i and that means k is not equal to i here I have P_{n_k} this term and concentrate only the n_i terms here and when $n_k = n_i$, so we have here P_{n_i} and I have q_{i0} , q_{j0} and this term already I have square root of $n_i n_j +$ square root of $n_i + 1 n_j + 1$ delta ij .

This mathematics may look little bit cumbersome but it is actually not that difficult but you will get a very useful result and it is important to know how to do this calculation. Now you see this particular term will give you simply 1 because for example any corresponding probabilities you have terms like this P_1 summation P_2 because of this product you will have all these probabilities would be equal to 1, this would be equal to 1, this would be equal to 1, this would be equal to 1.

So, overall from here it will be unity the whole thing and therefore I will be left out with only this term. So, let me write here you will have summation $n_i P_{n_i} q_{i0} q_{j0}$ and square root of $n_i n_j +$ square root of this. Again, let me write here and $n_j + 1$ delta ij .

(Refer Slide Time: 20:30)

$$\begin{aligned}
\sum_{i,j=1}^N \langle q_i q_j \rangle &= \sum_{i,j} \sum_{n_i} q_{i0} q_{j0} n_i [2n_i + 1] \\
&= \sum_i \sum_{n_i} q_{i0}^2 P_{n_i} (2n_i + 1) \\
\Rightarrow \sum_{i,j=1}^N \langle q_i q_j \rangle &= \sum_i q_{i0}^2 [2n(\omega_i) + 1] \\
n(\omega_i) &= \sum_{n_i} n_i P_{n_i}
\end{aligned}$$

Finally let me now sum it over all the oscillators finally if I sum up that means if I sum up over the variable ij for all the oscillators N oscillators, I have q i q j. So, this would be I can write it as i j and here I have n i and it is this particular term, let me put it here. I have to write it again. So, I will have q i0 q j0 square root of n i n j plus this one and delta i j fine.

So, this you can easily evaluate because of this kronecker delta I put i = j then I will be left out with only one summation. This is basically 2 summations are there. Now we are having one summation and then this summation over n i variables n i and then q i0 square and I will have I think I miss this term here that is P ni has to be also there. So, let me put it here. So, I have P ni or rather let me write it this way.

Then I have this term P ni also, I have to write. So, I have here P ni. Now because I take i = j, I will have q i0 square then I have P ni, so from here I will get ni and from here I will get ni + 1. So, this will give me 2 ni + 1. This I can further write as this I can write it as summation i q i0 square and this would be twice n of omega i, I will explain how I am getting it. So, this is what I will have.

Here this n of omega i is nothing but the average number of phonons for the ith oscillator and that is ni P ni, I think this you can recognize, I have just utilized this one. So, this is the expression I get. Now therefore this is a very important result I obtain ij when I takes the summation q i q j. This is what I got.

(Refer Slide Time: 23:44)

$$n(\omega_i) = \frac{1}{e^{h\omega_i/k_B T} - 1}$$

$$\sum_{i,j}^N \langle q_i q_j \rangle = \sum_i q_{i,0}^2 \coth\left(\frac{h\omega_i}{2k_B T}\right)$$

This one I can further simplify because I know that n of ω_i this already we worked out and this is equal to e to the power h cross ω_i by $K_B T - 1$. And if you put it here and do the analysis you will get it as this quantity position, position correlation term would turn out to be very straightforwardly you can work it out I encourage you to do it otherwise maybe we can do it in the problem-solving session, it is a simple algebra, you will get \coth hyperbolic h cross ω_i by twice $K_B T$. So, this is what we obtain. We will now discuss the quantum Langevin noise.

(Refer Slide Time: 24:34)

$$[\hat{q}_i, \hat{p}_j] = i\hbar \delta_{ij}$$

$$\hat{H} = \frac{\hat{p}^2}{2m} + \frac{1}{2} m \omega_m^2 \hat{z}^2 + \sum_{i=1}^N \left(\frac{\hat{p}_i^2}{2m_i} + \frac{1}{2} m_i \omega_i^2 \hat{z}_i^2 \right) - \hat{z} \sum_{i=1}^N c_i \hat{z}_i + \hat{z}^2 \sum_{i=1}^N \frac{c_i^2}{2m_i \omega_i^2}$$

$$\rightarrow \boxed{m \ddot{\hat{z}} + m \omega_m^2 \hat{z} + m \gamma_m \dot{\hat{z}} = \hat{\xi}(t)}$$

In the similar line as we did for classical Langevin noise, now both the system and the bath oscillator variables are now quantized and they follow this commutation relation say $q_i p_j$, this commutation is equal to $i\hbar$ cross δ_{ij} , the Hamiltonian for the system and bath combined together is now written in this form. So, this is exactly the same as you will see

except that now the position variable and the momentum variable are replaced by the corresponding operator.

So, this is the system part we have P^2 by $2m$ that is the kinetic energy then I have this potential energy of the system oscillator, $m\omega^2 q^2$ operators then these baths are considered to be a collection of N quantum harmonic, independent quantum harmonic, oscillators with corresponding momentum variable say p_i for the i th oscillator, m_i is the mass of the i th oscillator plus this potential energy term $\frac{1}{2}m_i\omega_i^2 q_i^2$ and then the interaction between the system and the bath oscillator is given by this particular term.

This is exactly what we wrote for the classical case as well and then we have this term is added there to take into account to cancel the effect of shifting of the frequency of the system oscillator. So, you have this term $c_i^2 m_i \omega_i^2$. Now using Heisenberg equation of motion we will again get equation of this form exactly the classical equation we get but now in the operator form $m\ddot{q} + m\omega^2 q + m\gamma\dot{q}$ that is equal to Langevin noise. Now this Langevin noise term is an operator.

(Refer Slide Time: 27:08)

$$\hat{x}(t) = \sum_{i=1}^N c_i \left[\hat{x}_i(0) \cos \omega_i t + \frac{\hat{p}_i(0)}{m_i \omega_i} \sin \omega_i t \right]$$

$$\hat{x}(t) = \hat{x}^+(t)$$

$$\hat{x}(t) \hat{x}(0) \neq \hat{x}(0) \hat{x}(t)$$

It is written in the operator form where this is same as in the classical case only it is the variables are now replaced by its operator. So, assuming that the coupling between the bath and the system to be weak then I can write this as $c_i \cos \omega_i t + \frac{p_i(0)}{m_i \omega_i} \sin \omega_i t$. Now it can be very easily verified that this quantum Langevin noise operator is Hermitian. So, $X_i(t) = X_i^\dagger(t)$ and also you can show that because of the

commutation you will see that $X_i(t) X_i(0)$ is not equal to $X_i(0)$ and product of $X_i(0) X_i(t)$.

(Refer Slide Time: 28:24)

$$= \sum_{ij} c_i c_j \left[\langle \hat{q}_i(0) \hat{q}_j(0) \rangle \cos \omega_i t \cos \omega_j t' + \frac{\langle \hat{q}_i(0) \hat{p}_j(0) \rangle}{m_j \omega_j} \cos \omega_i t \sin \omega_j t' + \frac{\langle \hat{p}_i(0) \hat{q}_j(0) \rangle}{m_i \omega_i} \sin \omega_i t \cos \omega_j t' + \frac{\langle \hat{p}_i(0) \hat{p}_j(0) \rangle}{m_i m_j \omega_i \omega_j} \sin \omega_i t \sin \omega_j t' \right]$$

Now we can calculate the auto correlation function for the quantum Langevin noise that is we have to calculate $X_i(t) X_i(0)$ and this would be in the similar line as in the case of the classical case let me first write the whole term $i j$ then I have here $c_i c_j$ and we will have $q_i(0) q_j(0)$ the expectation below the product then I have $\cos \omega_i t \cos \omega_j t'$. I will have 4 terms.

So, let me write all of them and I will have expectation value, all these are operators, I am not writing the operator's sign but you please understand that these are all operators. So, I have $q_i(0) q_j(0)$ here divided by $m_j \omega_j \cos \omega_i t \sin \omega_j t'$ and then I have plus $p_i(0) q_j(0)$ divided by $m_i \omega_i \sin \omega_i t \cos \omega_j t'$ and then plus $p_j(0) q_i(0)$ divided by $m_i m_j \omega_i \omega_j \sin \omega_i t \sin \omega_j t'$. So, this is what I will have. Now just a while back we have calculated these quantities.

(Refer Slide Time: 30:14)

$$\langle \hat{a}_i(0) \hat{a}_j(0) \rangle = \sum_{n_i} P_{n_i} a_{i0} a_{j0} \left[\sqrt{n_i n_j} + \sqrt{(n_i+1)(n_j+1)} \right] \delta_{ij}$$

$$\text{Similarly, } \langle \hat{b}_i(0) \hat{b}_j(0) \rangle = \sum_{n_i} P_{n_i} b_{i0} b_{j0} \left[\sqrt{n_i n_j} + \sqrt{(n_i+1)(n_j+1)} \right] \delta_{ij}$$

Here, $b_{i0} = \sqrt{\frac{\hbar m_i \omega_i}{2}}$

$b_{j0} = \sqrt{\frac{\hbar m_j \omega_j}{2}}$

Say q_{i0} , these are operators again we calculated q_{i0} average expectation value of this product of these 2 operators that we calculated as summation over $n_i P_{n_i} q_{i0} q_{j0}$ and we have it is square root of $n_i n_j + \text{square root of } n_i + 1 n_j + 1 \delta_{ij}$ and similarly you can show that you will get for this $p_{i0} p_{j0}$ that would be equal to summation n_i you have $P_{n_i} p_{i0} p_{j0}$ and this is the same it is square root of $n_i n_j + \text{square root of } n_i + 1 n_j + 1$ and you have δ_{ij} . However here this p_{i0} similarly for p_{j0} that would be $\hbar \text{ cross } m_i \omega_i$ by 2 square root or $p_{j0} = \hbar \text{ cross } m_j \omega_j$ by 2 square root.

(Refer Slide Time: 31:58)

$$\langle \hat{\xi}(t) \hat{\xi}(t') \rangle = \sum_{i=1}^N \frac{c_i^2}{2m_i \omega_i} \left[\coth\left(\frac{\hbar \omega_i}{2k_B T}\right) \cos \omega_i (t-t') - i \sin \omega_i (t-t') \right]$$

$$J(\omega) = \pi \sum_{i=1}^N \frac{c_i^2}{2m_i \omega_i} \delta(\omega - \omega_i)$$

/ §

Now using these relations we can work out the autocorrelation for the Langevin noise, quantum Langevin noise here because these are now operators, quantum operators and if the calculations are done you will see that you will get it as summation $i = 1$ to n $\hbar \text{ cross } c_i$ square divided by twice $m_i \omega_i$ and here you will have cot hyperbolic $\hbar \text{ cross the}$

reduced Planck's constant \hbar cross ω divided by $2 k_B T$, k_B is the Boltzmann's constant and here you have $\cos \omega (t - t')$ - $i \sin \omega (t - t')$.

So, this is what you will get. Again, as like in the classical case we can define the so-called spectral density function J of ω and that is exactly in the similar way we have it is π into summation over all the oscillators and I have c^2 divided by $2 m \omega \delta \omega - \omega$.

(Refer Slide Time: 33:28)

$$\langle \hat{x}(t) \hat{x}(t') \rangle = \frac{\hbar}{\pi} \int_0^{\infty} d\omega J(\omega) \left[\coth \left(\frac{\hbar \omega}{2 k_B T} \right) \cos \omega (t - t') - i \sin \omega (t - t') \right]$$

Now we can rewrite the autocorrelation function for the Langevin noise in terms of the spectral density function as this $X_i(t) X_i(t')$. This should be equal to you can just put it and you will get it as \hbar cross by π 0 to infinity you please look into the classical case once again and you will get it; it will be $\int_0^{\infty} d\omega j(\omega) \cot \text{hyperbolic} \hbar \omega$ cross ω by $2 k_B T \cos \omega (t - t')$ - $i \sin \omega (t - t')$. So, this is what you will get.

(Refer Slide Time: 34:22)

Ohmic Damping

$$J(\omega) = m\gamma_m \omega$$

$$\langle \hat{\xi}(t) \hat{\xi}(t') \rangle = \frac{m\gamma_m \omega_c}{\pi} \int_0^{\omega_c} d\omega \hbar \omega \left[\coth\left(\frac{\hbar\omega}{2k_B T}\right) \cos \omega(t-t') - i \sin \omega(t-t') \right]$$

Now as in the classical case here also let us go for Ohmic damping, because we are interested in Markovian process. So, for Ohmic damping if we consider Ohmic damping where this spectral density function is given as mass into gamma m omega we obtain the autocorrelation function expectation value of Xi of t Xi of t dash that would be equal to m into gamma m divided by pi integration d omega h cross omega coth hyperbolic h cross omega by 2 K B T cos omega t - t dash - i sine omega t - t dash.

Now here this integration limit is from 0 to generally we write of infinity but to be precise it is there is some cut-off frequency is there for Ohmic damping that is omega c and it is generally taken in the limit say omega c tends to infinity.

(Refer Slide Time: 35:47)

• In the classical limit: $\hbar \rightarrow 0$

$$\coth\left(\frac{\hbar\omega}{2k_B T}\right) \approx \frac{2k_B T}{\hbar\omega}$$

$\omega_c \rightarrow \infty$

$$\langle \hat{\xi}(t) \hat{\xi}(t') \rangle = 2m\gamma_m k_B T \delta(t-t')$$

$$\int_{-\infty}^{\infty} \omega \coth\left(\frac{\hbar\omega}{2k_B T}\right) \sin \omega(t-t') d\omega = 0$$

Now in the first approximation in the classical limit you know that in the classical case $\hbar \omega$ tends to 0 and temperature is non-zero, t is non-zero and \coth hyperbolic $\hbar \omega$ tends to $2k_B T$. This can be approximated to be as you can actually show it, it would be $2k_B T$ divided by $\hbar \omega$ and if we set $\omega \rightarrow \infty$ then you can very easily show that in the classical limit this autocorrelation function for the Langevin noise would be again will regain what we got in the classical case. That is $2\gamma m k_B T \delta(t - t')$.

So, this is what we obtain and in fact we must get it. Now there is actually another interesting form of this second moment of the quantum Langevin noise which you will often encounter in research literature and it is very easy to get it what is done there, you just have to utilize these facts and you can immediately rewrite it, you know that minus infinity to plus infinity $\omega \coth \hbar \omega$ $2k_B T \sin \omega(t - t')$. This integration is in the frequency domain, so you have here $d\omega$. So, this would be equal to 0 because overall this integrand this would be odd function.

(Refer Slide Time: 37:54)

$$\int_{-\infty}^{\infty} \omega \cos \omega(t-t') d\omega = 0$$

$$\langle \hat{x}(t) \hat{x}(t') \rangle = \frac{m\gamma m}{2\pi} \left[\int_{-\infty}^{\infty} d\omega \hbar \omega \coth \left(\frac{\hbar \omega}{2k_B T} \right) e^{-i\omega(t-t')} + \int_{-\infty}^{\infty} d\omega \hbar \omega e^{-i\omega(t-t')} \right]$$

And another fact you can utilize is say minus infinity to plus infinity $\omega \cos \omega(t - t')$ $d\omega = 0$. If you utilize these 2 properties then this autocorrelation function for the quantum Langevin noise can be written in a slightly different form that would be this. You will have $m\gamma m$ divided by 2π , you see here the limit is from ω say will you will put it as infinity then 0 to infinity we can replace it by a half of that is why this 2 term is coming; here we had $m\gamma m$ by π so I will have a half term here because now I am taking the limit from minus infinity to plus infinity.

So, that I can utilize these 2 properties there and what I will have is this, you will have it as it is very simple and straightforward you can verify it. $\int_{-\infty}^{\infty} d\omega \hbar \gamma_m \cot \text{hyperbolic} \hbar \text{cross} \omega \text{ by } 2 K B T$ then rather than writing here you have this \cos . So, I will write here e to the power $-i\omega t - t'$ because the sine part will give me 0 that is why I can do it and for the second term that means this particular term in the similar way I can utilize this particular property and then I can write it as minus infinity to plus infinity $\int_{-\infty}^{\infty} d\omega \hbar \gamma_m \cot \omega \text{ by } 2 K B T$ e to the power $-i\omega t - t'$ and this is what I will get.

(Refer Slide Time: 39:48)

$$\Rightarrow \langle \hat{X}(t) \hat{X}(t') \rangle = \hbar \gamma_m \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} e^{-i\omega(t-t')} \omega \left[\coth\left(\frac{\hbar\omega}{2k_B T}\right) + 1 \right]$$

$\tau = t - t'$
 $\hat{X}(t)$ is called stationary

$$\langle \hat{X}(\tau) \hat{X}(0) \rangle = \hbar \gamma_m \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} e^{-i\omega\tau} \omega \left[\coth\left(\frac{\hbar\omega}{2k_B T}\right) + 1 \right]$$

Or in short I can write it this very useful expression which you will encounter in many, many research literature or research paper it would be simply $\hbar \gamma_m \int_{-\infty}^{\infty} d\omega \cot \text{hyperbolic} \hbar \text{cross} \omega \text{ by } 2 K B T + 1$. I am just simplifying this expression and this is very popularly and very frequently used the second order moment or the auto correlation function for the quantum Langevin noise.

You can see that the autocorrelation function depends only on the time difference τ say time difference let me denote it by τ that is $\tau = t - t'$ as you can see from this term here. So, because it depends on the time difference only therefore this quantum Langevin noise X_i of t is called stationary and therefore we can in fact write it in this form also this autocorrelation function X_i of t X_i of 0 that would be equal to $\hbar \gamma_m \int_{-\infty}^{\infty} d\omega \cot \text{hyperbolic} \hbar \text{cross} \omega \text{ by } 2 K B T + 1$.

(Refer Slide Time: 42:03)

$$\begin{aligned}
S_{\xi\xi}(\omega) &= \int_{-\infty}^{\infty} d\tau \langle \xi(\tau)\xi(0) \rangle e^{i\omega\tau}; \quad \omega > 0 \\
&= m\hbar\gamma_m \int_{-\infty}^{\infty} d\tau \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} e^{i(\omega-\omega')\tau} \omega' \left[\coth\left(\frac{\hbar\omega'}{2k_B T}\right) + 1 \right] \\
&\quad \left| \frac{1}{2\pi} \int_{-\infty}^{\infty} d\tau e^{i(\omega-\omega')\tau} = \delta(\omega-\omega') \right.
\end{aligned}$$

Now the Fourier transform of this autocorrelator gives us the so-called spectral noise density in the quantum domain. That would be $S_{\xi\xi}(\omega)$ that is the Fourier transform of the autocorrelator, so $\xi(\tau)\xi(0)$ and the Fourier kernel $e^{i\omega\tau}$ we are evaluating it at for frequency say $\omega > 0$ and integrating over time; integration limit is from minus infinity to plus infinity.

We can quickly evaluate it is very simple so let us do that. We will just put the expression that we have derived for this autocorrelator that is $m\hbar\gamma_m \int_{-\infty}^{\infty} d\tau \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} e^{i(\omega-\omega')\tau} \omega' \left[\coth\left(\frac{\hbar\omega'}{2k_B T}\right) + 1 \right]$. Let me use the frequency variable say ω' $d\omega'$ by 2π $e^{i(\omega-\omega')\tau}$ because now I have here this $-\omega'$ is here.

So, doing it replacing by ω' . So, this is what I have then here I will have ω' I will have $\coth\left(\frac{\hbar\omega'}{2k_B T}\right) + 1$. This can be further simplified because you can recognize that what I have here is this Dirac delta function minus infinity delta function I will have if you look at it this expression I have a term like this integration $d\tau \frac{1}{2\pi} e^{i(\omega-\omega')\tau}$. This is nothing but the direct delta function $\delta(\omega-\omega')$.

(Refer Slide Time: 44:15)

$$= m\hbar\gamma_m \int_{-\infty}^{\infty} d\omega' \delta(\omega-\omega') \omega' \left[\coth\left(\frac{\hbar\omega'}{2k_B T}\right) + 1 \right]$$

$$\Rightarrow S_{\frac{1}{2}}(\omega) = m\hbar\gamma_m \left[\coth\left(\frac{\hbar\omega}{2k_B T}\right) + 1 \right]$$

$$\bullet \coth\left(\frac{\hbar\omega}{2k_B T}\right) = 2n(\omega) + 1$$

$$n(\omega) = \langle n \rangle = \frac{1}{e^{\hbar\omega/k_B T} - 1}$$

So, I can utilize it, if I utilize it then I will be able to write the whole thing as $m\hbar\gamma_m$ cross $\int_{-\infty}^{\infty} d\omega' \delta(\omega-\omega') \omega'$ - ω dash $\left[\coth\left(\frac{\hbar\omega}{2k_B T}\right) + 1 \right]$. Now using the property of the Dirac delta function I will get the spectral noise density for the quantum Langevin noise would be $m\hbar\gamma_m$ cross $\coth\left(\frac{\hbar\omega}{2k_B T}\right) + 1$.

So, this is what we obtain. Some time back we actually show that if you have worked out that this $\coth\left(\frac{\hbar\omega}{2k_B T}\right)$, I can write it in terms of the average number of phonon as $2n(\omega) + 1$ and just recall that $n(\omega)$ is nothing but the average number of phonon and it is given by $\frac{1}{e^{\hbar\omega/k_B T} - 1}$. So, if you utilize it then you can show that this function is nothing but $\coth\left(\frac{\hbar\omega}{2k_B T}\right) + 1$ is can be expressed in this form.

(Refer Slide Time: 46:02)

$$S_{\xi\xi}(\omega) = 2m\hbar\gamma_m\omega (n(\omega) + 1) \quad ; \quad \omega > 0$$

$$S_{\xi\xi}(-\omega) = \int_{-\infty}^{\infty} d\tau \langle \xi(\tau) \xi(0) \rangle e^{-i\omega\tau} \quad ; \quad \omega < 0$$

$$S_{\xi\xi}(-\omega) = 2m\hbar\gamma_m\omega n(\omega)$$

And using this we have the spectral noise density that would be in terms of the phonon number I have twice $m \hbar \gamma_m \omega$. So, this I got it. So, I think I missed something here, here I have this term ω is also there because I have used the Dirac delta function. So, that is how this ω term is coming and I will have here n of $\omega + 1$. So, this is what we obtain for when ω is greater than 0. On the other hand, I can also work out what is the spectral noise density at minus ω and in that case, it would be integration will be minus infinity to plus infinity $d\tau$ the Fourier transform of the correlator.

I have here and because it is ω is less than 0 in this case. So, I have minus rather than plus I have minus $i\omega\tau$. In this case I am having ω less than 0 and please do this calculation very straight forward the way we have done it. You can show you will get twice $m \hbar \gamma_m \omega$. Now you are going to get n of ω not this $+1$ would not come. So, this is what you will get $S_{\xi\xi}$ at minus ω .

(Refer Slide Time: 47:48)

$$S_{\frac{z}{z}}(\omega) \neq S_{\frac{z}{z}}(-\omega) \quad \text{Not symmetric}$$

In the classical limit: $\hbar \rightarrow 0$
 $k_B T \gg \hbar \omega$,

$$n(\omega) \approx \frac{k_B T}{\hbar \omega}$$

$$\begin{cases} S_{\frac{z}{z}}(\omega) = 2m\gamma_m k_B T \\ S_{\frac{z}{z}}(-\omega) = 2m\gamma_m k_B T \end{cases}$$

So, it is clear that this spectral noise density in the quantum regime is not symmetric. This is what the first thing we obtained in what is different from the classical regime. So, this spectral noise density function is not symmetric. However, in the classical limit you can show because you know that in the classical limit your \hbar tends to 0 and your $k_B T$ is much, much greater than $\hbar \omega$.

And in that case, you can have this average phonon number can be written as $k_B T$ divided by $\hbar \omega$ and utilizing this you can show that this spectral noise density function in the classical limit would be twice $m \gamma_m k_B T$ and if it is evaluated at minus ω this will also give you twice $m \gamma_m k_B T$. So, in the classical domain this spectral noise density function would be symmetric.

(Refer Slide Time: 49:19)

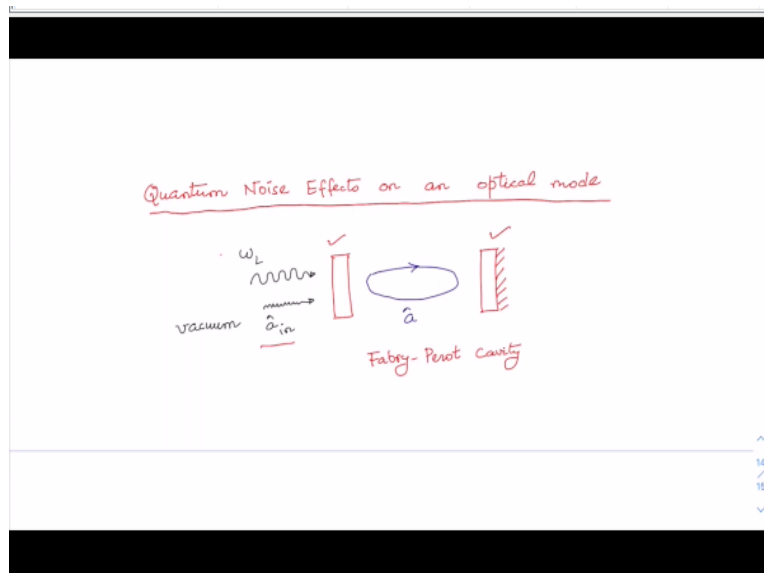

→ If temp is high, but $\hbar \neq 0$
 we can write approximately:

$$\begin{cases} S_{\frac{z}{z}}(\omega) = 2m\gamma_m \hbar \omega_m [n(\omega_m) + 1] \\ S_{\frac{z}{z}}(-\omega) = 2m\gamma_m \hbar \omega_m n(\omega_m) \end{cases}$$

One thing we can do here if say temperature is very high but you are still in the quantum limit say but your $\hbar \omega$ is not equal to 0 then we can write very approximately and this is going to be useful later on approximately this spectral noise density function, quantum noise density function as $2m\gamma m \hbar \omega$.

Now this n of ω is evaluated at the mechanical frequency $\omega_m + 1$ or the resonance frequency of the mechanical system oscillator and $S_{\xi\xi}$ at the frequency minus ω this would be $2m\gamma m \hbar \omega$ you will have n evaluated at ω_m . Now let us come to our Fabry-Perot cavity which is the main setup for cavity optomechanical system and let us see how the quantum noise affects an optical mode.

(Refer Slide Time: 50:43)

So, we are going to study optical noise effects on an optical mode. This actually comes under the so-called input output theory as well, You know that the optical mode undergoes damping inside the Fabry-Perot cavity and the electromagnetic fluctuation from vacuum outside the cavity inject quantum noise into the cavity and in the case of cavity optomechanics the cavity is often driven by a single mode laser having frequency say ω_L .

We will consider these environmental effects for a single sided cavity as depicted here in this schematic diagram where one of the mirrors is perfectly reflecting. Say this one is perfectly reflecting while the other one is weakly transmittive. We will begin our analysis with a Hamiltonian that I am now going to write in the Heisenberg picture.

(Refer Slide Time: 51:49)

$$\begin{aligned}
 H &= \hbar \omega_{\text{opt}} \hat{a}^\dagger \hat{a} + \sum_i \hbar \omega_i \hat{b}_i^\dagger \hat{b}_i + \hbar \Omega_{\text{drive}} (\hat{a}^\dagger e^{-i\omega_L t} + \text{h.c.}) \\
 &+ \sum_i \hbar (\Omega_i \hat{a} \hat{b}_i^\dagger + \Omega_i \hat{a}^\dagger \hat{b}_i) \\
 [\hat{b}_i, \hat{b}_j^\dagger] &= \delta_{ij} \\
 &\cdot i\hbar (\Omega_{\text{drive}} \hat{a}^\dagger e^{-i\omega_L t} - \Omega_{\text{drive}}^* \hat{a} e^{i\omega_L t}) \\
 \boxed{H} &= \hbar \omega_0 \hat{a}^\dagger \hat{a} + \sum_i \hbar \omega_i \hat{b}_i^\dagger \hat{b}_i + i\hbar (\Omega_{\text{drive}} \hat{a}^\dagger e^{-i\omega_L t} - \Omega_{\text{drive}}^* \hat{a} e^{i\omega_L t}) \\
 &+ \sum_i \hbar (\Omega_i \hat{a} \hat{b}_i^\dagger + \Omega_i \hat{a}^\dagger \hat{b}_i)
 \end{aligned}$$

Let me first write down the full Hamiltonian $H = \hbar \omega_{\text{opt}} \hat{a}^\dagger \hat{a}$. This is the Hamiltonian which denotes the energy of the optical mode in the cavity, where ω_{opt} is the resonance, cavity resonance frequency. Then we have another term that is summation over all bath oscillators, $\hbar \omega_i \hat{b}_i^\dagger \hat{b}_i$. So, this term describes the energy of the bath oscillators in fact these are electromagnetic oscillators.

This vacuum we are now modeling it as a collection of independent harmonic oscillators and it surrounds this optical cavity only with the constraint that it has to have is that $[\hat{b}_i, \hat{b}_j^\dagger] = \delta_{ij}$, this commutation relation has to be satisfied $[\hat{b}_i, \hat{b}_j] = 0$ and then we will have another term that is it is now driven by a laser from outside. So, that is taken into account by $\hbar \Omega_{\text{drive}} \hat{a}^\dagger e^{-i\omega_L t} + \text{h.c.}$ this is the driving amplitude.

And we have this term $\hat{a}^\dagger \hat{a}$ a photon is created inside the cavity and the laser frequency is ω_L and it should be Hermitian. So, therefore there is a term Hermitian conjugate and many times this particular term is people write it in this form also. Say $\hbar \Omega_{\text{drive}} \hat{a}^\dagger e^{-i\omega_L t} + \text{h.c.}$ because here the drive amplitude is considered to be a real quantity, but it may be a complex quantity because it has a phase part so people write it in this form also, $\hbar \Omega_{\text{drive}} \hat{a}^\dagger e^{-i\omega_L t} + \text{h.c.}$

This Ω_{drive} is complex $\Omega_{\text{drive}} e^{-i\omega_L t}$. So, this is another form and in fact it is the most general form and maybe let us consider this particular form rather than this one here we will come to that and there will be another term that would be summation over

all the bath oscillators $\hbar \omega_i a^\dagger b_i + \omega_i a b_i$. So, this particular term actually refers to the fact that there is a coupling between the system and bath.

And the strength of the coupling between the cavity mode and the i th bath oscillator mode is given by ω_i . So, this is the usual coupling and we will now go to analyze it but as I said let me rewrite the whole Hamiltonian in this form and this is what we are going to analyze. Rather than writing ω_{opt} , so let me just put $\hbar \omega_0$ here that is the optical cavity resonance frequency, $\hbar \omega_0 a^\dagger a + \sum_i \hbar \omega_i b_i^\dagger b_i$ and then let me now take the general form here.

That is $i \hbar \omega_{drive} a^\dagger e^{-i \omega_{drive} L t} - \omega_{drive} a e^{i \omega_{drive} L t}$ and finally we have $\sum_i \hbar \omega_i$. So, please do not get confused with ω terms here, this is ω_{drive} and this is the ω_i , ω refers to the coupling between the optical cavity and the bath oscillator. So, what this particular term says that when a optical cavity is getting annihilated and this is getting resulted in the creation of a bath mode or opposite process can also happen.

So, this is basically is happening due to the coupling between this bath oscillator mode and the optical mode. So, we are now going to analyze this particular Hamiltonian and this will give us lot of insight about what is going on as regard quantum noise effect in an optical mode is concerned. Let me stop here for today. In this lecture we discussed about the quantum Langevin noise, we have worked out the autocorrelation function for the quantum Langevin noise.

And also, we saw that the quantum spectral noise density is not symmetric unlike its classical counterpart and finally we started discussing on the effect of quantum noise on an optical mode in a Fabry-Perot cavity and will continue this very important discussion in the next class. So, see you in the next class, thank you.
