Lec10: Quantum Measurements

(Refer Slide Time: 02:47)

Hello, welcome to lecture 1 of module 3. This is lecture number 7 of this course. In this lecture we are going to discuss about quantum measurement process and this concept is extremely important in the context of quantum entanglement as you will see later and this measurement process in quantum mechanics is fundamentally different from the classical measurement process. Please note that the classical information theory is formulated independently of the measurement of the system. This is because of the reason that you are always going to get the same result if the system processes the same information which is totally different in the quantum information processing. So let us discuss about measurements now and you will find this concept a little bit technical but I try to give as much example as possible. So let us begin. Measurement is basically an experimental procedure meant to determine the value of a physical observable. That's what we mean by measurement. So it's an experimental procedure to determine the value of a physical observable and this procedure has to be such, in fact it has to be carefully designed so that it should be this procedure should be such, it should be such that the observable being

measured being measured does not get altered. And in quantum mechanics measurement has a very important role and it's a it's a very critical concept.

(Refer Slide Time: 04:47)

it should be such that the observable being measured does not get altered.

$|\psi\rangle$
state

eigenstate $|a_i\rangle$

$\hat{A} :$

Eigenvalue a
eigenket $|a\rangle$

$$P(a) = |\langle a | \psi \rangle|^2$$

4:47 / 1:04:28

By making a measurement on the system what we mean by in quantum mechanics is that we project the system state vector into one of the basis vector that the measurement equipment defines. Let us say we have this is pictorially speaking suppose this is my system and this system is in the state say ket psi and by making a measurement what is done is that this state vector ket psi is projected into one of the one of the eigenvalues let us say a_i so and the corresponding eigenstate say eigenstate ket a_i . So because of the measurement this state vector ket psi is projected into one of the eigenstate a_i and measurement of an observable suppose anyway all of us we already know that any physically observable quantity is always represented by an operator in quantum mechanics and measurement of an observable a of a system in the state psi yields an eigenvalue a of the operator and corresponding eigenstate is say ket ket a suppose because of the measurement eigenvalue i get is eigenvalue we get is a and the corresponding eigen ket is ket a and the probability of getting the eigenvalue probability of getting the eigenvalue a is given by mod square of this quantity right this is what we know it is also one of the postulates of quantum mechanics.

(Refer Slide Time: 06:05)

Handwritten notes on a video player showing the measurement process and the definition of a projection operator.

$$|\psi\rangle \xrightarrow{\text{measure } \hat{A}, \text{ obtain } a} |a\rangle$$

Projection operator

$$\hat{P}_a = |a\rangle\langle a|$$
$$|\psi\rangle = \sum_i c_i |i\rangle$$

6:05 / 1:04:28

So basically measurement causes the state of the system ket psi to collapse into an eigenstate ket a so if you say measure the observable a then you are going to obtain the eigenvalue a or in other words you the state is getting collapse into the eigen ket a to describe this process by an operator acting on the state generally we introduce the so-called projection operator.

So projection operator i think most of you may know just let us have a quick recap what we mean by projection operator once again so the action it's basically action of the projection operator is to project the state along another state suppose the projection operator let me define is say this one ket a bra a so this is the projection operator and if suppose my state is ket psi and i can write it as a superposition of eigenkets say this is the superposition principle.

(Refer Slide Time: 07:15)

Handwritten notes on a video player showing the action of a projection operator on a state.

$$\hat{P}_a = |a\rangle\langle a|$$
$$|\psi\rangle = \sum_i c_i |i\rangle$$
$$\hat{P}_j |\psi\rangle = |j\rangle\langle j| \sum_i c_i |i\rangle$$
$$= \sum_i |j\rangle c_i \underbrace{\langle j|i\rangle}_{\delta_{ji}}$$
$$= c_j |j\rangle$$

7:15 / 1:04:28

Then the projection operator say P_j if it is operated on the state vector ket ψ what it is going to result is this projection operator P_j is ket j bra j and it operates on ket ψ which is the superposition of the eigenkets uh like this right and i can now write this quantity as follows i can write it as say ket j and this i am having c_j is just a number and i have δ_{ji} so this quantity is nothing but kronecker delta δ_{ji} so because of this i am going to get simply c_j so as you see the projection operator P_j projects the state vector along the direction of the ket j okay.

(Refer Slide Time: 08:44)

$$\begin{aligned}
 & \cdot \hat{P}_j^2 = \hat{P}_j \\
 & \cdot \hat{P}_i \hat{P}_j = \delta_{ij} \hat{P}_j \\
 & \cdot \sum_i \hat{P}_i = \mathbf{1} = \sum_i |i\rangle \langle i| \\
 & \cdot \hat{P}_i^\dagger = \hat{P}_i
 \end{aligned}$$

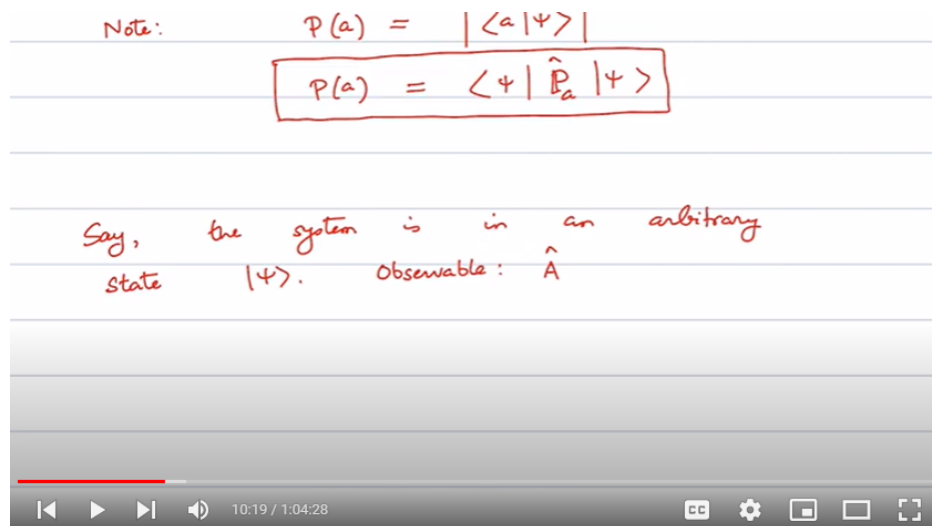

And there are many properties of projection operator some of the notable properties are very easy to prove for example if you can easily verify it P_j squared is equal to P_j right that it's very easy to see another property is the projection operators are mutually orthogonal if you have two projection operator different projection operators say P_i and P_j and it's we equal to delta δ_{ij} P_j that means if i is not equal to j then the $P_i P_j$ product is going to give you zero and projection operators this is very important projection operators are complete basically these are projectors so you have this is basically the so-called completeness condition because this is equal to identity operator and in fact it is easy to see that this results is because P_i is nothing but ket i bra i and as we know that this is nothing but the so-called completeness condition and also projection operators because has to be hermitian and it is also easy to see P_i^\dagger is equal to P_i okay this is Hermitian.

(Refer Slide Time: 10:19)

Note: $P(a) = |\langle a | \psi \rangle|^2$

$P(a) = \langle \psi | \hat{P}_a | \psi \rangle$

Say, the system is in an arbitrary state $|\psi\rangle$. Observable: \hat{A}

Note this particular it's very easy to see also that the probability of getting the eigenvalue a if the state is in the system is in the arbitrary state ket ψ the probability of getting the eigenvalue a would be given by mod square of this quantity and which actually I can write also as this $\langle \psi | \hat{P}_a | \psi \rangle$ okay so the projection operator \hat{P}_a projects ket ψ into eigenstate ket a and the probability is can be written in this in terms of projection operator this can be written very simply by this expression. Now let us understand the measurement process a bit more clearly to do that let us say a system is in an arbitrary state ket ψ say the system is in an arbitrary state ket ψ okay and the observable is represented by operator we are interested in measuring an observable and this observable is represented by the operator \hat{A} .

(Refer Slide Time: 12:17)

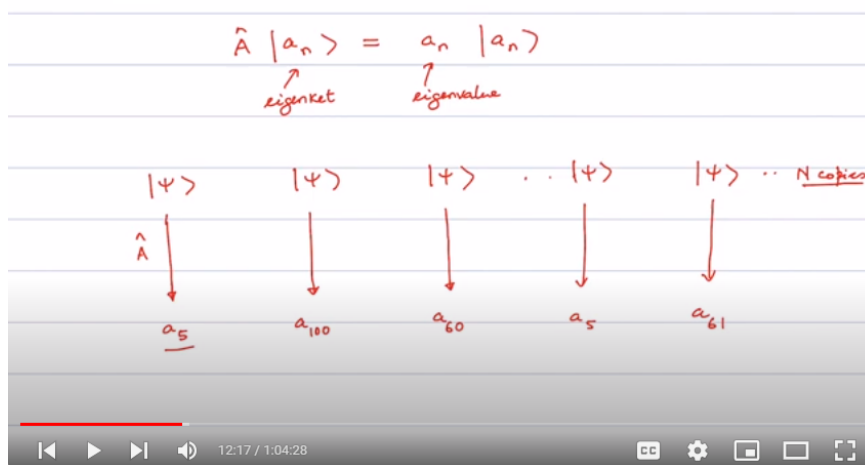

$\hat{A} |a_n\rangle = a_n |a_n\rangle$

↑ eigenket ↑ eigenvalue

$|\psi\rangle$ $|\psi\rangle$ $|\psi\rangle$.. $|\psi\rangle$ $|\psi\rangle$.. N copies

↓ \hat{A} ↓ ↓ ↓ ↓ ↓

a_5 a_{100} a_{60} a_5 a_{61}

And this operator \hat{A} satisfy the eigenvalue equation $\hat{A} \ket{a_n}$ is equal to $a_n \ket{a_n}$ and a_n these are as you can see these are eigenkets and this is your eigenvalue okay and measurement of the observable A on the system yields any of the eigenvalues right okay let me make you understand it by this.

Suppose we have a number of copies of the system and the system is in the state $\ket{\psi}$ suppose we have N number of copies like this $\ket{\psi} \ket{\psi}$ like this N number of identical copies N copies we have okay N number of copies we have the same system exact system and we are making a measurement on the system and basically the observable A and if we measure make a measurement then because of the measurement if I make an individual measurement on $\ket{\psi}$ then I may get any one of the eigenvalues eigenvalues let us say I get the eigenvalue say a_5 if I make another measurement on this $\ket{\psi}$ suppose I get this time a 100 all identical copies I have I make measurement on each one each of them at the same time then I am going to get sometime I will get a say 60 and suppose I make sometimes I may again get say a_5 as I have got it here and like this okay suppose I here get again suppose a 60 or say 61 and so on any of the eigenvalues okay.

(Refer Slide Time: 14:15)

Say, we get λ_m , p_m no. of times

If $N \rightarrow \infty$, then fraction of measurements that give λ_m :

$$\frac{p_m}{N} \rightarrow P(\lambda_m)$$

14:15 / 1:04:28

Then if suppose some eigenvalues because of this numerous number of measurements some eigenvalues you are getting again suppose some number of times let us say say you get suppose say we get say we get the eigenvalue λ_m p_m number of times p_m number of times okay that's the frequency at which we get the eigenvalue $p_m \lambda_m$ p_m number of times we get now if say N is very large suppose N tends to infinity the number of copies of the system is very large then the fraction of measurement then fraction of measurements fraction of measurements so this is fraction of measurements that give that give λ_m is simply we get it p_m number of times and N number of copies we

have right so this is what we are going to have and this basically is nothing but the probability of getting the eigenvalue λ_m .

I hope you are getting the idea in other words what i mean to say is that quantum mechanics tells us the rate at which we will obtain a particular outcome when we have an infinite number of copies of the same exact systems okay.

(Refer Slide Time: 16:06)

QM tells us that the rate at which
we will obtain a particular outcome when we
have an infinite no. of copies of the same
exact system.

$$\hat{A} |a_n\rangle = a_n |a_n\rangle$$
$$|\psi\rangle = \sum c_n |a_n\rangle$$
$$c_n = \langle a_n | \psi \rangle$$

So basically quantum mechanics tells us quantum mechanics tells us that the rate this is important the rate at which the rate at which we will obtain we will obtain a particular a particular outcome when we have an infinite number number of copies of the same exact system this is important to understand because the essence of measurement is hidden here in this particular statement that i have written here let me make a little bit of more elaboration here.

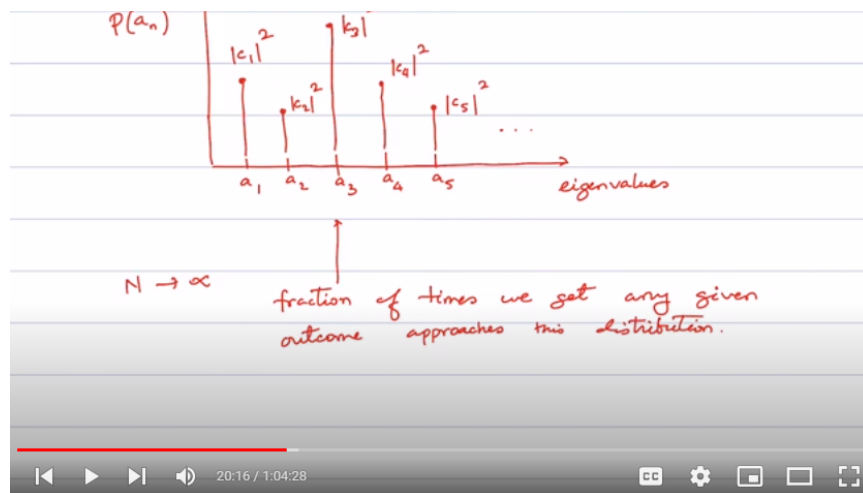

Suppose if we have just one copy right rather than n number of copies if we just have one copy we can only know the probability of getting a particular outcome so if we have say this eigenvalue equation say a_n a_n this means that if the system is in an arbitrary state ket ψ and which i can write it as a superposition of the eigenkets like this where c_n is a complex coefficient and by now you know that c_n i can write it as $a_n \psi$ right.

(Refer Slide Time: 18:57)

So the probability of getting the eigenvalue a_n is simply the modulus squared of the coefficient c_n in the expansion of the state $|\psi\rangle$. This is nothing but $|c_n|^2$. So now the process of measurement can be actually described pictorially as follows. Suppose let me draw the x-axis and y-axis. On the x-axis, let me put the eigenvalues. Okay, suppose I have these eigenvalues $a_1, a_2, a_3, a_4, a_5, \dots$ on the x-axis. Along the y-axis, let me put the corresponding probabilities. Suppose $P(a_n)$ is the probability of getting a particular eigenvalue. So the system is in an arbitrary state $|\psi\rangle$ and these eigenvalues depend on the operator A only. Okay, it depends on the operator A only and it does not depend on the state $|\psi\rangle$. Now each eigenvalue has a particular height given by the square of the absolute value of the coefficient. Suppose the probability of getting a_1 is going to be given by $|c_1|^2$ and in this diagram it would have some height corresponding to a_1 . The probability is $|c_1|^2$ corresponding to a_2 , the probability would be $|c_2|^2$. Corresponding to a_3 , let us say it is $|c_3|^2$ and so on. Corresponding to a_4 , it may be the height $|c_4|^2$. For a_5 , it may be like this, right? It would be $|c_5|^2$. It would be $|c_5|^2$ and so on. That's how you will get. So basically what you are getting is a probability distribution. It's a probability distribution that you are basically obtaining here. And higher the height, higher is the probability of obtaining that particular eigenvalue. So if we have a very large number of copies of the exact system, that means ideally, say $N \rightarrow \infty$.

(Refer Slide Time: 20:16)

If n tends to infinity a very large number of exact copies of the system we have the fraction of time we get any given outcome approaches this particular distribution okay the this particular probability distribution means the what i mean to say is that the fraction of times we get any given outcome any given outcome approaches this distribution. I hope you get the idea here however for any individual measurement we cannot know beforehand what will be the outcome okay unlike classical physics in quantum mechanics we cannot predict the precise outcome of measurement of a physical quantity instead what quantum mechanics tells us is the precise probability distribution of all possible outcomes of that measurement.

(Refer Slide Time: 23:10)

in the state $|\psi\rangle$ is

$$p(m) = \langle \psi | \hat{M}_m^\dagger \hat{M}_m | \psi \rangle$$

•
$$\sum_m \hat{M}_m^\dagger \hat{M}_m = 1$$

• The state immediately after the measurement is

$$|m\rangle = \frac{\hat{M}_m |\psi\rangle}{\sqrt{p(m)}} = \frac{\hat{M}_m |\psi\rangle}{\sqrt{\langle \psi | \hat{M}_m^\dagger \hat{M}_m | \psi \rangle}}$$

Now to be more formal we construct a measurement operator say M_m such that the probability of obtaining an outcome m in the state $|\psi\rangle$ is given by this expression $\langle \psi | M_m^\dagger M_m | \psi \rangle$ which is probability of obtaining the outcome m is given by the expectation value of $M_m^\dagger M_m$ this is the expression and here M_m as I said is the measurement operator and this measurement operator satisfy the completeness condition $\sum_m M_m^\dagger M_m = I$ and the state which we can get immediately after measurement is given by the state immediately after the measurement is $M_m |\psi\rangle / \sqrt{\langle \psi | M_m^\dagger M_m | \psi \rangle}$ this will be more clear to you if I give you an example I will give you very soon now the state immediately after the measurement is $M_m |\psi\rangle / \sqrt{\langle \psi | M_m^\dagger M_m | \psi \rangle}$ this is the measurement operator M_m and divided by square root of $\langle \psi | M_m^\dagger M_m | \psi \rangle$ okay or if I write the full expression then this would be $M_m |\psi\rangle$ and here I have expectation below this $\langle \psi | M_m^\dagger M_m | \psi \rangle$ I'm not going to write the operator sign again and again so I'm just writing here but later on I will avoid to put a uh you know this sign here cap sign okay now let me give an example so these are these two are very important result this is also in fact this is also these three are very important result in the context of measurement operators.

(Refer Slide Time: 24:36)

Example

$$|\psi\rangle = a|0\rangle + b|1\rangle$$

$$M_0 = |0\rangle\langle 0|$$

$$M_1 = |1\rangle\langle 1|$$

$$p(0) = \langle \psi | M_0^\dagger M_0 | \psi \rangle$$

To give you an example let us say we have a superposition state like this $|\psi\rangle$ it's a qubit state it's a superposition of $|0\rangle$ and $|1\rangle$ and a and b are the complex coefficient and we measure this particular state to see if it is in the state $|0\rangle$ or $|1\rangle$ okay so the measurement operators here we define them like this we have we have two measurement operators and these are the projection operators one is $|0\rangle\langle 0|$ like this and another measurement operator is M_1 that would be $|1\rangle\langle 1|$ these are the two projection operators and getting the outcome 0 that means getting the the system in the

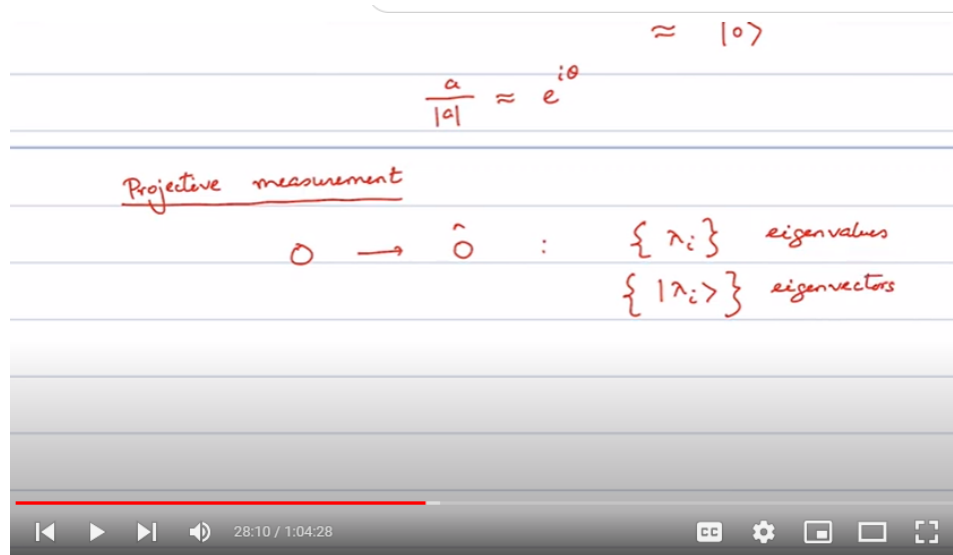

state ket 0 so we said it is p of 0 there's a probability of getting the state to be in the in the ket state 0 is given by this expression now it will be m0 dagger m0 ket psi.

(Refer Slide Time: 26:33)

$$\begin{aligned}
 p(0) &= \langle \psi | M_0^\dagger M_0 | \psi \rangle & \left. \begin{aligned} & M_0^\dagger M_0 \\ &= (|0\rangle\langle 0|) |0\rangle\langle 0| \\ &= |0\rangle\langle 0| \end{aligned} \right\} \\
 &= \langle \psi | 0 \rangle \langle 0 | \psi \rangle \\
 &= |\langle 0 | \psi \rangle|^2 \\
 \Rightarrow p(0) &= |a|^2 \\
 |0\rangle &= \frac{M_0 |\psi\rangle}{\sqrt{p(0)}} = \frac{|0\rangle\langle 0 | \psi \rangle}{\sqrt{|a|^2}} = \frac{a |0\rangle}{|a|} \\
 &\approx |0\rangle
 \end{aligned}$$

Okay let us open it up so if you open it up first of all as you can see m0 dagger m0 is simply it is m0 dagger is m0 is ket 0 bra 0 right and m0 dagger is the opposite of that so that would be simply this one this is your m0 dagger and which is same as m0 and now we have simply ket 0 bra 0 and therefore here let me put ket 0 bra 0 psi and this guy is nothing but modulus of modulus square of this quantity and this is again nothing but mod of a square this is basically a known result to us i'm just showing you the application of this measurement operator and as i said the state immediately after the measurement is now ket 0 so as per our definition we have m0 ket psi divided by p of 0 square root of p of 0 which is we have m0 is ket 0 bra 0 applied on ket psi and divided by square root of mod a square right p p0 this we have already worked out and this implies that we are going to have it would be simply a0 right divided by mod mod a okay so this is actually nothing but this is nothing but the state ket 0.

(Refer Slide Time: 28:10)

Similarly for the other case m_1 we can have it now here you just have to note that the quantum state is defined up to a phase and here this quantity a by mod a it can be at the max $e^{i\theta}$ the power some phase factor would be there and anyway this phase factor as you know it's not going to play any role here.

Now let us discuss about the projection measurement and which is a special case of the generalized measurement scheme so we are now going to discuss about projection or basically not projection let me the terminology appropriate terminology would be projective measurement projective measurement which is a special case of the generalized measurement okay so say to understand that let us we have an observable O and which can be of course observable O it's represented by an operator \hat{O} in the quantum mechanics and this has say eigenvalues are say λ_i and the corresponding orthonormal eigenvectors are represented by ket $|\lambda_i\rangle$ like this right this is what the set of eigenvalues corresponding to the observable O and these are its eigenvectors.

(Refer Slide Time: 29:34)

The image shows a video player with a handwritten derivation on lined paper. At the top right, the set of eigenvectors is written as $\{|\lambda_i\rangle\}$ with the word "eigenvectors" written next to it. Below this, the identity operator $\hat{O} = \hat{O}I$ is expressed as a sum over eigenvectors: $\hat{O} = \hat{O}I = \sum_{i=1}^n \hat{O} |\lambda_i\rangle \langle \lambda_i|$. This equation is then boxed, resulting in $\hat{O} = \sum_i \lambda_i |\lambda_i\rangle \langle \lambda_i|$. At the bottom, two projection operators are defined: $M_m = |\lambda_m\rangle \langle \lambda_m|$ and $M_m^\dagger = |\lambda_m\rangle \langle \lambda_m|$. The video player interface at the bottom shows a progress bar at 29:34 / 1:04:28 and various control icons.

So in that case I can now represent this operator the so-called spectral decomposition I can do this we have done and it's actually it's very simple also you can have i is equal to 1 to say n or ∞ and this is your λ_i λ_i okay this is the completeness condition I am using $\sum \lambda_i$ because the eigenvalue equation is going to be satisfied so therefore I can write \hat{O} operator \hat{O} is equal to \sum over i here it will be λ_i this is an eigenvalue it is λ_i ket $|\lambda_i\rangle$ bra $\langle \lambda_i|$ okay the operator anyway I can represent it in this form it's called known as the spectral decomposition of the operator now let us make the measurement operator I am talking about projective measurement so let me define a operator M_m measurement operator in this form so $M_m = |\lambda_m\rangle \langle \lambda_m|$ and the corresponding uh its hermitian conjugate would be again as you can see it would be ket $|\lambda_m\rangle$ bra $\langle \lambda_m|$.

(Refer Slide Time: 30:58)

$$M_m = |\lambda_m\rangle\langle\lambda_m|$$
$$M_m^\dagger = \langle\lambda_m|\langle\lambda_m|$$
$$\sum_m M_m^\dagger M_m = 1$$

Probability for a given outcome m of a measurement:

$$\langle\psi|M_m^\dagger M_m|\psi\rangle$$
$$= \langle\psi|\lambda_m\rangle\langle\lambda_m|\psi\rangle$$

It's very easy to see that sum over all this thing is nothing but if you just do it m m dagger m you will find that this is identity so therefore this particular property of measurement operator is anyway satisfied by this projective operator also.

Now the probability for a given outcome it's a kind of repetition but we are doing it in the context of projective measurement probability maybe later on it will be more clear to you if i give more examples and i will do that so for probability for a given outcome for a given outcome m of a of a measurement let me write m as m t for measurement is then expectation value as i we have this result general result this is what you will have and this in the case of projective or this thing what we are having this is ψ and this is λ_m right and this is again λ_m ket ψ .

(Refer Slide Time: 32:04)

$$\langle\psi|M_m^\dagger M_m|\psi\rangle$$
$$= \langle\psi|\lambda_m\rangle\langle\lambda_m|\psi\rangle$$
$$= |\langle\lambda_m|\psi\rangle|^2 \checkmark$$

• state after msmt:

$$\frac{M_m|\psi\rangle}{\sqrt{\langle\psi|M_m^\dagger M_m|\psi\rangle}} = \frac{|\lambda_m\rangle\langle\lambda_m|\psi\rangle}{\sqrt{|\langle\lambda_m|\psi\rangle|^2}}$$

This guy is nothing but modulus squared of this quantity $\langle \lambda_m | \psi \rangle$ modulus squared okay which is exactly the absolute square of the expansion coefficient of ket $|\psi\rangle$ for that eigenstate.

Now what about the state after measurement so this is one result we have and state after measurement M_m that means measurement is going to be M_m ket $|\psi\rangle$ divided by square root of $P(M)$ which is here $\langle \psi | M_m^\dagger M_m | \psi \rangle$ right so if i open it up then you will get it would be $\langle \lambda_m | \lambda_m \rangle$ ket $|\psi\rangle$ divided by square root of this result already we have so let us put it that would be modulus square of this quantity inside the bracket $\langle \lambda_m | \psi \rangle$ modulus squared.

(Refer Slide Time: 33:14)

. state after measurement .

$$\begin{aligned} \frac{M_m |\psi\rangle}{\sqrt{\langle \psi | M_m^\dagger M_m | \psi \rangle}} &= \frac{|\lambda_m\rangle \langle \lambda_m | \psi \rangle}{\sqrt{|\langle \lambda_m | \psi \rangle|^2}} \\ &= \frac{\langle \lambda_m | \psi \rangle}{|\langle \lambda_m | \psi \rangle|} |\lambda_m\rangle \\ &= e^{i\theta} |\lambda_m\rangle \end{aligned}$$

So from here i get it as this is just a number right this is just a number so let me write $\langle \lambda_m | \psi \rangle$ it's a complex number divided by $\langle \lambda_m | \psi \rangle$ okay and this is $\langle \lambda_m | \lambda_m \rangle$ and this as you can see it is nothing but $e^{i\theta}$ because this is a complex number i can always write it as $e^{i\theta}$ into the modulus of this quantity this modulus get cancelled out and you'll be left out with $e^{i\theta}$ $\langle \lambda_m | \lambda_m \rangle$ okay here θ is an arbitrary phase and just like $|\lambda_m\rangle$ is the is an eigenstate similarly $e^{i\theta} |\lambda_m\rangle$ is also an eigenstate of the observable O or the operator O .

(Refer Slide Time: 34:21)

Density operator

Pure state

$$\rho = |\psi\rangle\langle\psi|$$
$$p(m) = \langle\psi|M_m^\dagger M_m|\psi\rangle$$
$$p(m) = \text{Tr}(\rho M_m^\dagger M_m)$$

34:21 / 1:04:28

Okay so this generalized measurement scheme can easily be actually generalized to density operator as well so let me now extend this concept to the case of density operator formalism also extended to density operator case first let me do that for pure state that is very easy and simple actually it's very straightforward and as you know a pure state is represented by density operator ρ is equal to this ket ψ bra ψ and therefore the probability of an outcome p of m is going to be this is our result from generalized measurement scheme so i can now write it in the using because this is nothing but the average right kind of expectation value and we know from our density matrix formalism this i can write is as trace $\rho M_m^\dagger M_m$ so this is the result i have in the in terms of density operator now.

(Refer Slide Time: 36:14)

$$|\phi\rangle = \frac{M_m |\psi\rangle}{\sqrt{\langle\psi|M_m^\dagger M_m|\psi\rangle}}$$
$$P_{out} = |\phi\rangle\langle\phi| = \frac{M_m |\psi\rangle\langle\psi| M_m^\dagger}{\langle\psi|M_m^\dagger M_m|\psi\rangle}$$
$$P_{out} = \frac{M_m \rho M_m^\dagger}{\text{Tr}(\rho M_m^\dagger M_m)}$$

36:14 / 1:04:28

Now what about the state when the state changes after a measurement with result m the density operator the density operator corresponding to okay first let me write the state after measurement as you we know that we are going to get the state to be say this one let me name it as say ket ψ_i after measurement i get the state to be like this i have this ψ_i $\langle \psi_i |$ dagger ρ_{ii} ket ψ_i the corresponding density operator that means at the output after the measurement i would get you will just for pure state is very simple this is what you will have and if i open it up what i am going to get is this ρ_{ii} ket ψ_i this bra ψ_i $\langle \psi_i |$ dagger divided by in fact you will get two terms and square root will go away and you will be left out with ρ_{ii} dagger ρ_{ii} ket ψ_i very straightforward i think all of you can see this and this would be the output that means the after measurement the state would be the density operator would be ρ_{ii} ρ_{ii} dagger divided by trace of ρ_{ii} ρ_{ii} dagger okay so this is also an important result and this we have got in the context of a pure state but the extension to the mixed state is also very straightforward and in the case of mixed states we are going to get actually the similar result.

(Refer Slide Time: 37:59)

Mixed state

$$\rho = \sum_i p_i |\psi_i\rangle \langle \psi_i|$$

$$= \sum_i p_i \rho_i$$

- The joint probability for the system to be in the pure state $|\psi_i\rangle$ and measuring a result m_i

So let me just quickly discuss that as well for mixed state our density operator for mixed state is given by this expression p_i is the probability ket ψ_i ket bra ψ_i so this is the density operator for the mixed state and this actually i can write as sum over i 's this is probability this is probability p_i and this i can write the density operator for the pure state gets ψ_i right ket ψ_i i can write it the density operator ρ_i is referring to the density operator corresponding to the pure state ket ψ_i so this is the expression i can write now the joint probability let me write because you see in the case of mixed state two probabilities are involved here one is the so-called classical probability and then the quantum case which we have discussed in great detail when we have discussed density operator

formalism now the joint probability for the system to be in the pure state $|\psi_i\rangle$ and the measurement result to be m is

(Refer Slide Time: 40:04)

$$p_i p(m|i)$$
 Total probability:

$$p(m) = \sum_i p_i \text{tr}(\rho_i M_m^\dagger M_m)$$

$$= \text{tr}\left(\sum_i p_i \rho_i M_m^\dagger M_m\right)$$

$$p(m) = \text{tr}(\rho M_m^\dagger M_m)$$

And measuring the result measuring a result say m is it would be first this is the probability p_i that is the probability to pick up the pure state $|\psi_i\rangle$ and then getting the result m outcome m is $p(m|i)$ at say i right when you have picked up $|\psi_i\rangle$ and then getting the outcome so this is basically the joint probability and now you have to sum over all i 's to get the total probability for getting the outcome m as a result of measurement so total probability total probability total probability of getting the outcome m right because you have so many pure states are involved here every pure state is designated by one particular $|\psi_i\rangle$ so you have to sum over all i 's there and if you sum over all i 's then here you have p_i and this quantity for pure state case you have already know that will be trace of $\rho_i M_m^\dagger M_m$ so this is what you will get.

And this is very straightforward and very simple because of trace operation I can write trace here and put the summation side inside the trace operation trace operator then we have sum over i I have here $p_i \rho_i$ please note the symbol carefully okay this ρ_i I'm writing kind of an *ρ* in italicized way for you know density operator thing and I have here $M_m^\dagger M_m$ and this is nothing but as you can see this is trace of $\rho M_m^\dagger M_m$ okay so as you see once again we get the familiar expression that we have obtained for pure state also same expression similar expression.

(Refer Slide Time: 41:39)

$$= \text{tr} \left(\sum_i p_i \rho_i M_m^\dagger M_m \right)$$
$$\boxed{p(m) = \text{tr} (\rho M_m^\dagger M_m)}$$

The new state:

$$\rho_{\text{out}} = \sum_i p_i \frac{M_m |\psi_i\rangle \langle \psi_i| M_m^\dagger}{\text{tr} (\rho M_m^\dagger M_m)}$$
$$\boxed{\rho_{\text{out}} = \frac{M_m \rho M_m^\dagger}{\text{tr} (\rho M_m^\dagger M_m)}}$$

The new state after measurement of the mixed state becomes this also you are going to get exactly the similar one i don't want to elaborate on it more but you can check it yourself this would be again you have to sum over all i's here you have this p_i and then you have M_m ket $|\psi_i\rangle$ right and $\langle \psi_i| M_m^\dagger$ this we have done for pure state case and here you have trace of $\rho M_m^\dagger M_m$ and this is going to result in this particular expression $M_m \rho M_m^\dagger$ divided by trace of $\rho M_m^\dagger M_m$ so here only expression looks similar only point you have to keep in mind is that this density operator ρ that i am writing here refers to the mixed state and if it is a pure state then you have to write the density operator pertaining to the pure state okay. So as you can see the general measurement scheme covers all operations that can be performed on a quantum system.

(Refer Slide Time: 43:27)

Measurement of the POVM kind

$$\hat{E}_m = M_m^\dagger M_m, \quad \sum_m \hat{E}_m = 1$$

The probability of outcome 'm' on making a measurement on the state ρ is

$$p(m) = \text{Tr} (\rho \hat{E}_m)$$

Many times we are not interested in the post measurement state of the system but we are interested in the statistics or the relative probabilities of outcome that we can collect by making a measurement on an ensemble this we can generally do by the so-called povm or positive operator value measurement formalism let us discuss it measurement of the povm kind let us consider the set of operators say E_m is equal to $M_m^\dagger M_m$ and of course all measurement operators whatever it is they have to satisfy this particular condition so this has to be identity and the probability of outcome m right on making a measurement on making a measurement let me write m as m_t so this is i mean by this i mean measurement on the state measurement on the state ρ is $p(m)$ is equal to $\text{trace } \rho E_m$ this already we know right and obviously for pure state.

(Refer Slide Time: 44:46)

In the case of pure state:

$$p(m) = \langle \psi | \hat{E}_m | \psi \rangle$$

Example 1

$$\hat{P}_m \hat{P}_{m'} = \delta_{mm'} \hat{P}_m$$

$$\sum_m \hat{P}_m = \mathbf{1}$$

The slide also features a video player interface at the bottom with a progress bar and control icons.

In the case of pure state in the case of pure state this particular expression will simply boil down to expectation value of this operator E_m in the state ket ψ okay let me illustrate this povm by an example couple of example first let me begin with a trivial example say consider a projective measurement described by measurement operator P_m these are projectors such that $P_m P_{m'}$ because you know the projection operators are orthogonal orthonormal $\delta_{mm'} P_m$ this we already know and also sum over these operators is equal to 1 or identity.

(Refer Slide Time: 45:28)

$$p(m) = \langle \psi | E_m | \psi \rangle$$

Example 2

$$\hat{P}_m \hat{P}_{m'} = \delta_{mm'} \hat{P}_m$$
$$\sum_m \hat{P}_m = \mathbb{1}$$
$$\hat{E}_m = \hat{P}_m + \hat{P}_m = \hat{P}_m \quad \left(\text{Here, all POVM elements are the same as measurement operators themselves} \right)$$

45:28 / 1:04:28

In this case all povm elements are same as measurement operators themselves because here E_m is equal to $P_m^\dagger P_m$ and which is nothing but P_m itself right so here in this particular example all povm elements all povm elements are the same as measurement same as measurement operators themselves operators themselves.

(Refer Slide Time: 46:34)

Example 2

$$|\psi\rangle = \frac{1}{\sqrt{2}} (|0\rangle + |1\rangle)$$

The POVM elements are:

$$E_1 = |0\rangle\langle 0|, \quad E_2 = |1\rangle\langle 1|$$
$$\sum_m E_m = E_1 + E_2 = \mathbb{1}$$

46:34 / 1:04:28

Maybe let me give you an another example this may not be very appropriate to you so let us say another example consider this one let us say ket ψ is equal to a state is given it's a qubit system it is in a superposition of ket 0 plus ket 1 this plus ket 1 this qubit state what are the povm elements here it's also a trivial and you know what are the povm elements here povm elements are two elements are there one is projector ket 0 bra 0 and

another one is e_2 is ket 1 bra 1 and it's very clear that sum over all these projectors which is basically e_1 and e_2 e_1 plus e_2 should be equal to identity event right.

(Refer Slide Time: 47:46)

outcome 1 : getting the state $|+\rangle$ in $|0\rangle$
outcome 2 : getting the state $|+\rangle$ in $|1\rangle$

$$p(1) = \langle + | e_1 | + \rangle$$
$$= \frac{1}{\sqrt{2}} (\langle 0 | + \langle 1 |) \left(\frac{1}{\sqrt{2}} (|0\rangle + |1\rangle) \right)$$
$$= \frac{1}{2}$$

47:46 / 1:04:28

And there are two outcomes of the measurement so outcome outcome one two outcomes first outcome is say getting the state ket psi this qubit state in the state ket 0 and the second outcome that say outcome number two is getting the state ket psi in ket 1 okay and what about the corresponding probabilities probability of getting the outcome one is given by this expression and you can easily work it out it's very trivial so let me still work it out it is $\frac{1}{2}$ by root 2 bra psi is bra 0 plus bra 1 here and e_1 is this projector ket 0 bra 0 and ket psi is $\frac{1}{\sqrt{2}}$ ket 0 plus ket 1 and as you can very easily see that this is going to be equal to simply half right.

(Refer Slide Time: 48:59)

Sy. $p(2) = \frac{1}{2}$

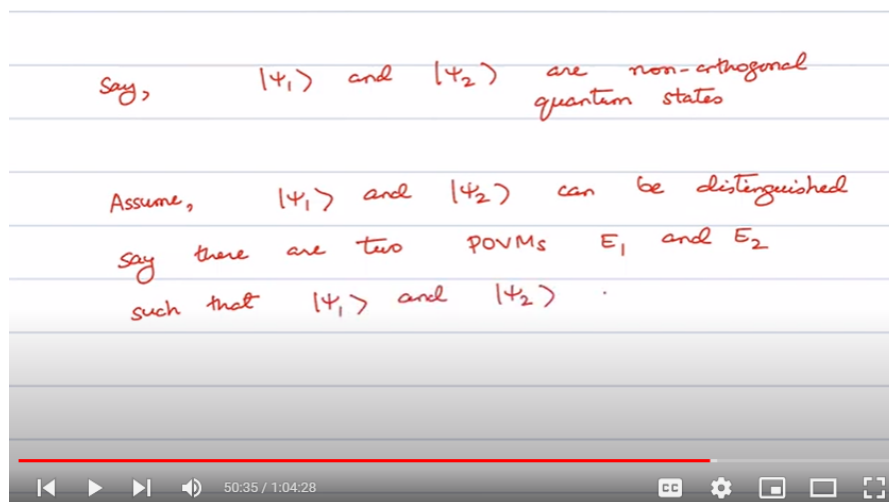

Non-orthogonal quantum states cannot be distinguished

48:59 / 1:04:28

So similarly you can make it out that probability of getting the second outcome is also half and these results are already known to you because there is a 50/50 probability of getting the state either in ket 0 or ket 1. I just have illustrated you only by this example.

You can see the importance of POVMs when I talk about one important theorem or in quantum mechanics in particular related to measurement problem and this theorem is this that non-orthogonal quantum states cannot be reliably distinguished. Non-orthogonal quantum states cannot be distinguished and this has very important replication in quantum information processing and many experiments so let us actually prove it.

(Refer Slide Time: 50:35)

To prove that let me let me argue it otherwise let us say we have ket psi 1 and ket psi 2 and these are two non-orthogonal states say ket psi 1 and psi 2 are non-orthogonal non-orthogonal quantum states okay they are non-orthogonal quantum states and we will assume rather than assuming that because we have to prove that they cannot be distinguished so let us assume otherwise that assume ket psi 1 and ket psi 2 can be distinguished okay can be distinguished if this is not we are going to actually going to get some kind of a contradiction.

Now say there are two POVMs there are two POVMs two experiments are there to say there are two POVMs two measurements E_1 and E_2 such that such that they can be distinguished such that psi 1 and psi 2 can be distinguished can be distinguished reliably.

(Refer Slide Time: 52:33)

• Prob. ($|\psi_1\rangle, 1$) = $\langle \psi_1 | E_1 | \psi_1 \rangle = 1$
• Prob. ($|\psi_2\rangle, 2$) = $\langle \psi_2 | E_2 | \psi_2 \rangle = 1$
• Prob. ($|\psi_2\rangle, 1$) = $\langle \psi_2 | E_1 | \psi_2 \rangle = 0$
• Prob. ($|\psi_1\rangle, 2$) = $\langle \psi_1 | E_2 | \psi_1 \rangle = 0$

Now, $\langle \psi_1 | E_2 | \psi_1 \rangle = 0$
 $\Rightarrow \sqrt{E_2} |\psi_1\rangle = 0$

52:33 / 1:04:28

What does that mean this means that the probability of measuring ket psi 1 and getting the outcome 1 is 100 so you are going to get psi 1 e1 psi 1 is equal to 1 and probability of measuring ket psi 2 and getting the second outcome outcome 2 is also 100 that means psi 2 e2 psi 2 is equal to 1 or that also mean this is important results that also mean the probability of measuring psi 2 and getting the outcome is has to be is 0 so psi 2 e1 psi 2 is equal to 0 and probability of measuring the state measuring ket psi 1 and getting the outcome 2 is going to be 0 psi 1 e2 psi 1 is equal to 0 okay so this is what we mean that if psi 1 and psi 2 can be distinguished reliably by two povms e1 and e2. Now you see let us analyze it a bit further now we have this expression psi 1 e2 psi 1 is equal to 0 from here one can easily obtain square root of e2 psi 1 is equal to 0.

(Refer Slide Time: 53:36)

$\Rightarrow \sqrt{E_2} |\psi_1\rangle = 0$

Since $|\psi_2\rangle$ is not orthogonal to $|\psi_1\rangle$

$$|\psi_2\rangle = \alpha |\psi_1\rangle + \beta |\phi\rangle$$
$$|\alpha|^2 + |\beta|^2 = 1$$

Then,

$$\sqrt{E_2} |\psi_2\rangle = \alpha \sqrt{E_2} |\psi_1\rangle + \beta \sqrt{E_2} |\phi\rangle$$

53:36 / 1:04:28

This is trivial to see this is what you are going to get now since ket psi 1 psi 2 is not orthogonal is not orthogonal to psi 1 ket psi 1 so therefore psi 2 can be decomposed actually into two components one component parallel to psi 1 and another component orthogonal to psi 1 so one component orthogonal parallel to psi 1 and other component is say phi which is orthogonal to psi 1 so this is what you should get of course with the condition that mod alpha square plus mod beta square has to be equal to 1.

So what is what is the you know result of this thing this means that then what you will have then you can see that square root of e2 psi 2 psi 2 i'm now writing it as alpha psi 1 plus beta phi so let me just write it alpha square root of e2 psi 1 plus beta square root of e2 ket phi okay.

(Refer Slide Time: 56:09)

$$= \beta \sqrt{E_2} |\phi\rangle$$

$$\Rightarrow \langle \psi_2 | E_2 | \psi_2 \rangle = |\beta|^2 \langle \phi | E_2 | \phi \rangle$$

$$\leq |\beta|^2 \sum_i \langle \phi | E_i | \phi \rangle$$

$$\leq |\beta|^2 \left[\begin{array}{l} p(i) = \langle \phi | E_i | \phi \rangle \\ \sum_i p(i) = 1 \\ \Rightarrow \sum_i \langle \phi | E_i | \phi \rangle = 1 \end{array} \right]$$

$$\Rightarrow \boxed{\langle \psi_2 | E_2 | \psi_2 \rangle < 1}$$

Now this is going to be equal to simply beta beta square root of e2 it would be beta square root of e2 phi because this guy is anyway equal to 0 by the end of this expression right so therefore we'll be left out with this one and this implies from here i can write psi 2 e2 psi 2 right this would be equal to mod beta square and you will have phi e2 phi i think this is also trivial to see and of course this has to be less than or equal to mod beta square if i take sum over all e i's all e's then i have this right e i phi.

Okay now this has to be less than or equal to mod beta square why because because you know the probability of the outcome i is in the state shape ket phi because of the measurement e i is this and sum of all probabilities is has to be unity one okay so therefore it means that you should have sum over i phi e i phi is equal to one okay this is going to be equal to one so that's why it is less than mod beta square but this has to be less than one because mod alpha square plus mod beta square is equal to one so mod beta square has to be less than one okay but okay so what you get is this result you get but earlier what you have obtained this you got but earlier you got this expression that this you have taken it to

be equal to one because you were able to distinguish ψ_1 and ψ_2 that is that is your assumption but what you have what resulted because of all these assumption you are getting in contradiction. So this is this is a contradiction this is a contradiction so what does it mean this means that we cannot we cannot reliably distinguish orthogonal states orthogonal states actually non-orthogonal states right we cannot reliably distinguish non-orthogonal states ket ψ_1 and ket ψ_2 .

(Refer Slide Time: 58:08)

Example 3

Alice gives Bob :

$$|\psi_1\rangle = |0\rangle \quad \text{and} \quad |\psi_2\rangle = \frac{|0\rangle + |1\rangle}{\sqrt{2}}$$

Now as a final example to illustrate POVM formalism let me give you this example let us say Alice gives Bob a qubit prepared in one of the two states that may say ψ_1 is equal to ket 0 and ket ψ_2 is equal to ket 0 plus ket 1 by root 2 okay now you can see that ket ψ_1 and ket ψ_2 are non-orthogonal so Bob find it impossible to determine whether he is given ket ψ_1 or ket ψ_2 with perfect reliability however it is possible to for Bob to perform a measurement which distinguishes the state some of the time but never makes an error of misidentification.

(Refer Slide Time: 59:14)

consider a POVM containing three elements :

$$E_1 = \frac{\sqrt{2}}{2 + \sqrt{2}} |1\rangle\langle 1|$$

$$E_2 = \frac{\sqrt{2}}{2 + \sqrt{2}} \frac{(|0\rangle - |1\rangle)(\langle 0| - \langle 1|)}{2}$$

$$E_3 = I - E_1 - E_2$$

To understand that let us consider a POVM containing three elements consider a POVM containing three elements containing three elements very cleverly chosen elements given as this e_1 is equal to $\frac{1}{\sqrt{2}}$ ket 1 bra 1 this is one measurement one POVM element other one is e_2 is equal to $\frac{1}{\sqrt{2}}$ ket 0 bra 0 minus ket 1 bra 1 divided by 2 and e_3 is equal to $I - e_1 - e_2$.

(Refer Slide Time: 1:00:34)

• $\sum_m E_m = 1$

Say, Bob is given $|\psi_1\rangle = |0\rangle$
 He makes a msmt described by
 POVM $\{E_1, E_2, E_3\}$

• The probability that Bob will get
 the result E_1 is zero

1:00:34 / 1:04:28

It's very trivial and straightforward to see that sum of all EMs because this guy has to be satisfied whenever you are considering some measurement operators this has to be equal to 1 so they form a legitimate POVM.

Now say Bob is given the state ket psi 1 okay ket psi 1 is equal to ket 0 he makes a Bob makes a measurement he makes a measurement described by this measurement described by these three POVM elements POVM which are e_1 e_2 and e_3 okay.

Now the probability the probability probability very easy to see that probability that Bob will get the result e_1 is 0.

(Refer Slide Time: 1:01:52)

POVM $\{E_1, E_2, E_3\}$

- The probability that Bob will get the result E_1 is zero

$$\langle \psi_1 | E_1 | \psi_1 \rangle = 0$$

\Rightarrow If the result of Bob's msmt is E_1 , then Bob can safely say that the state received by him must have been $|\psi_2\rangle$

1:01:52 / 1:04:28

You can see that because if you find out this expectation value $\langle \psi_1 | E_1 | \psi_1 \rangle$ if you work it out because E_1 already I as I have defined here you see E_1 if you take the operations ket $|\psi_1\rangle$ is ket $|0\rangle$ you can immediately see this is going to be 0 what does it mean this implies that if the result of his measurement is E_1 if the if the result of Bob's measurement if Bob's measurement is E_1 then then Bob can safely say Bob can safely safely say that the state provided by state received by received by him or provided by Alice to him must be must have been what must have been $|\psi_2\rangle$ not $|\psi_1\rangle$ right that's what it mean and in fact you can see if you can work out $\langle \psi_2 | E_1 | \psi_2 \rangle$ you will find that this is going to be non-zero so therefore Bob has received the step $|\psi_2\rangle$ instead of $|\psi_1\rangle$.

(Refer Slide Time: 1:03:04)

$$\langle \psi_2 | E_1 | \psi_2 \rangle \neq 0$$

- On the other hand, if the msmt outcome is E_1 , then it must have been the state $|\psi_1\rangle$

Because:

$$\langle \psi_2 | E_2 | \psi_2 \rangle = 0$$
$$\langle \psi_1 | E_2 | \psi_1 \rangle \neq 0$$

1:03:04 / 1:04:28

On the other hand on the other hand on the other hand if the measurement if the measurement outcome is e_2 measurement outcome is e_2 then then it must have been have been the state $|\psi_1\rangle$ that Bob has received right because because if you again mathematically see that if you calculate $\langle \psi_2 | e_2 | \psi_2 \rangle$ you will find it to be 0 and you will find $\langle \psi_1 | e_2 | \psi_1 \rangle$ is non-zero similar argument now sometime what may happen is this sometime Bob may get may get e_3 and then Bob would not be able to then Bob cannot distinguish or cannot actually conclude cannot conclude what state is given to him what state is given to him I hope by this example you have seen the power of POVM measurements let me stop for today in this lecture we have discussed about quantum measurement process in the next lecture we are going to discuss about entanglement measures related to discrete variables so see you in the next lecture thank you so much.
