Lecture - 9
Angular Momentum in Quantum Mechanics
Dimensionality of the Direct-Product (Composite) Vector Space
Angular Momentum Coupling Clebsch-Gordan Coefficients:
Recursion Relations

(Refer Slide Time: 00:21)

$\vec{j} = \vec{j}_1 + \vec{j}_2$

Direct product basis
 $\{|j_1 m_1\rangle | j_2 m_2\rangle\} = \{|j_1 m_1 j_2 m_2\rangle\}$
 $= \{|(j_1 j_2) m_1 m_2\rangle\}$
 $= \{|m_1 m_2\rangle\}$

Dimensionality of the basis?
 "uncoupled"

$m_1 = -j_1, -j_1 + 1, \dots, j_1 - 1, j_1$
 $m_2 = -j_2, -j_2 + 1, \dots, j_2 - 1, j_2$
 dimensionality : $(2j_1 + 1) \times (2j_2 + 1)$

2012-August PCD-STIAP Unit 2 106

Greetings, we considered the coupling of Angular Momenta j_1 and j_2 . And we recognized that each of these has got a vector representation in a basis, which is $2j_1 + 1$ dimensional, so there is a $2j_1 + 1$ dimensional basis, for j_1 and the $2j_2 + 1$ dimensional basis for j_2 . And the uncoupled basis will have a product dimension of $2j_1 + 1$ times $2j_2 + 1$, these spaces are individually completely disjoint, they have no common parts. Because, angular momentum j_1 and j_2 are completely independent of each other, each component of j_1 would commute with each component of j_2 . And we are now composing from these individual spaces, the product space and the product space will be the composite space, which is made up of the individual spaces of j_1 and j_2 , right.

(Refer Slide Time: 01:31)

$\vec{J} = \vec{J}_1 + \vec{J}_2$

Dimension of the "coupled" basis?

Eigenfunctions of the coupled Ang. Mom.

$\vec{J}: [j^2, j_z] = 0$

Eigenbasis: $\{ |(j_1 j_2) jm) \} \equiv \{ |jm) \}$

$j^2 |(j_1 j_2) jm) = \hbar^2 j(j+1) |(j_1 j_2) jm)$

$j_z |(j_1 j_2) jm) = \hbar m |(j_1 j_2) jm)$

2012-August PCD-STAP Unit 2 107

So, now if you look at the left hand side, which is the net angular momentum coming from, the sum of these 2 and this is the new type of sum this is not just the vector addition, because it is an addition of 2 quantum vector operators. We certainly expect that, this space of the coupled angular momentum will have the same dimensionality as the product space, because it is coming from that.

So, we anticipate the answer to be $2j_1 + 1$ times $2j_2 + 1$, but that is not obvious from, what we are looking at the only thing, we know from this is that, this j will have $2j + 1$ degeneracy coming from the isotopic right. So, it will have m quantum number, which will go from minus j to plus j , so there will be a $2j + 1$ dimensional dimensionality that will come from that, but that will have to be compounded by some additional factor, which is coming from the values that, j can take. Because, we have to find out what kind of values j can take and that will give us the net dimensionality of the coupled angular momentum.

(Refer Slide Time: 02:58)

$\vec{J} = \vec{J}_1 + \vec{J}_2$

Dimension of the "coupled" basis?

$\vec{J}: [\vec{J}^2, J_z]_- = 0$

Eigenbasis: $\{ |(j_1, j_2) jm) \} = \{ |jm) \}$

$m = -j, -j+1, \dots, j-1, j$ for every $j: j_{\min} \leq j \leq j_{\max}$

$|j_1 - j_2| \leq j \leq (j_1 + j_2)$

Triangle inequality: it has a simple proof

2012-August PCD-STAP Unit 2 108

So, the coupled angular momenta, I am representing by these curved brackets and uncoupled by angular brackets, that is just for convenience, now this we know, that m can go from minus j to plus j , so there will be $2j + 1$ values. J quantum number j , this will have a certain ray from a minimum to a maximum, but we do not know exactly, what this value of min minimum is and what is the maximum values that something, which we probably know from some of the other courses.

And we perhaps know it from some literature that, we have red, but we are going to determine exactly, what this value of j_{\min} should be, so that it will not be an assumption in our minds. So, we will find out, what j_{\min} can be and what j_{\max} can be and it will turn out that the minimum value is modulus of j_1 minus j_2 and the maximum value will be j_1 plus j_2 and we will prove this particular inequality that, we have in front of us.

(Refer Slide Time: 04:08)

Eigenbasis of direct product of uncoupled vectors

Alternative orthonormal basis sets $\{ |j_1 m_1\rangle |j_2 m_2\rangle \} = \{ |j_1 m_1 j_2 m_2\rangle \}$
 $= \{ |(j_1 j_2) m_1 m_2\rangle \}$
 $= \{ |m_1 m_2\rangle \}$

$\vec{j} = \vec{j}_1 + \vec{j}_2 : [j^2, j_z]_- = 0$

Eigenbasis of coupled angular momentum $\{ |m_1 m_2\rangle \}$

$\{ |(j_1 j_2) j m\rangle \} = \{ |j m\rangle \}$ **Transformations**

$j^2 |(j_1 j_2) j m\rangle = \hbar^2 j(j+1) |(j_1 j_2) j m\rangle$ $\{ |j m\rangle \}$
 $j_z |(j_1 j_2) j m\rangle = \hbar m |(j_1 j_2) j m\rangle$

2012-August FCD-STAP Unit 2 109

So, essentially we are dealing with alternative orthonormal basis sets, one is the basis of the uncoupled vectors, which is the direct product of uncoupled vectors, so these are the angular kates and you can compose the product basis. In brief you can suppress the notation $j_1 j_2$ and simply write these as $m_1 m_2$, so this is the $m_1 m_2$ basis and then you also have the alternate basis, which is the Eigen basis of the coupled angular momentum, which is j and this is the Eigen basis of j^2 and j_z , these 2 operators, since they commute with each other. These are the 2 simultaneously diagonalizable operators, so you can consider transformation from 1 basis to another, because an arbitrary vector, you can always express, as a Leneous of proposition of any basis that, it does not matter, which it is.

(Refer Slide Time: 05:11)

$$\begin{aligned}
 I_{\text{op}} &= \sum_{i=i_{\min}}^{i_{\max}} |i\rangle\langle i| \\
 |jm\rangle &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 |jm\rangle &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 &\quad \uparrow \\
 &\text{Clebsch-Gordan Coefficient (CGC)} \\
 \langle m_1 m_2 | jm\rangle &\equiv \langle j_1 m_1 j_2 m_2 | (j_1 j_2) jm\rangle
 \end{aligned}$$

So, let us represent this coupled vector, which is written here as well, but it is operated upon by the unit operator and I have decomposed the unit operator, this is the resolution of unity, as we call it. In the basis of the product of uncoupled vectors, $m_1 m_2$ are the product vectors from the uncoupled basis, so this is the resolution of unity and you find that this expression amounts to a linear superposition of these $m_1 m_2$ vectors, scaled by these scalars that, you find in these bracket.

These brackets has got an angular bracket on 1 side and a curved bracket, on the other, but essentially it is a bracket, it is a scalar and whether it is angular or circular is just a matter of convenient notation, there is no big physics in it. It is just a Scaler and these Scalers are known as the Clebsch Gordan coefficients, in general these can be some complex numbers, but they turn out to be real, as we will see. And these are the Clebsch Gordan coefficients, you can write them in the complete notation inclusive of $j_1 j_2$ and this is the coupled vector $j m$ coming from $j_1 j_2$, and you can insert the j_1 and j_2 quantum numbers on this side, as well just for completeness.

(Refer Slide Time: 06:51)

$$|jm\rangle = \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle$$

$$|(j_1 j_2) jm\rangle = \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |(j_1 j_2) m_1 m_2\rangle \langle m_1 m_2 (j_1 j_2) | jm\rangle$$

Equivalent, alternative, notation

$$|(j_1 j_2) jm\rangle = \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |j_1 m_1 j_2 m_2\rangle \langle j_1 m_1 j_2 m_2 | (j_1 j_2) jm\rangle$$

2012-August PCD-STAP Unit 2 111

So, here we have this expression along with the Clebsch Gordan coefficients, either in the brief notation or in the complete comprehensive notation, again some books write $j_1 j_2$ over here and then $m_1 m_2$, some other books write $j_1 m_1$ and then $j_2 m_2$. So, this is just a matter of choice, the actual physical content of both of these notations is exactly the same. So, sometimes you know different books on quantum mechanics, you know Merzbacher Sharif and so on, they use slightly different notations, so no big deal about it, just keep track of what is the physical content, which is going into the labels.

(Refer Slide Time: 07:43)

Inverse transformations I_{op}

$$|m_1 m_2\rangle = \sum_{j=j_{min}}^{j_{max}} \sum_{m=-j}^j |jm\rangle \langle jm | m_1 m_2\rangle$$

$$|m_1 m_2\rangle = \sum_{j=j_{min}}^{j_{max}} \sum_{m=-j}^j |jm\rangle \langle jm | m_1 m_2\rangle$$

Clebsch-Gordan Coefficient (CGC)

$m = -j, -j+1, \dots, j-1, j$

To be proved shortly

$$\begin{cases} j = |j_1 - j_2|, \dots, (j_1 + j_2 - 1), (j_1 + j_2) \\ j_{min} = |j_1 - j_2| & j_{max} = (j_1 + j_2) \end{cases}$$

2012-August PCD-STAP Unit 2 112

So, you know construct the inverse transformations, we had expressed the coupled vectors in terms of the uncoupled product vectors, now we do the inverse transformations and on the left hand side, we have got the product of uncoupled vectors, which is now expressed, in terms of the coupled vector, because you can simply pre multiply the same vector $m_1 m_2$ by the resolution of the unit operator, but this resolution is now carried out in the coupled basis.

And therefore, what you find over here is an expansion in terms of the vectors of the coupled, angular momentum and then again you have coefficients, which play a similar role as the coefficients that, you saw earlier, so they are again the Clebsch Gordan coefficients. And you know that in this basis at m will go from minus j to plus j that is coming from isotropy of space, because axis of quantization can be anywhere right.

So, you have a $2j + 1$ for degeneracy coming from the m quantum number and the j itself will go from a certain minimum value to a maximum value and what we are going to prove now that, this minimum value is the modulus of $j_1 - j_2$ and the maximum value is $j_1 + j_2$. So, that is what we are about to prove now.

(Refer Slide Time: 09:20)

$$|jm\rangle = \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle$$

$$(j_1 j_2) jm\rangle = \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |(j_1 j_2) m_1 m_2\rangle \langle m_1 m_2 (j_1 j_2) | jm\rangle$$

Equivalent, alternative, notation

$$(j_1 j_2) jm\rangle = \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |j_1 m_1 j_2 m_2\rangle \langle j_1 m_1 j_2 m_2 | (j_1 j_2) jm\rangle$$

2012-August
PCD STIAP Unit 2
113

So, let us see how the proof goes, so this is the coupled angular momentum and this again, you can write in alternative complete notation, either by writing $j_1 j_2$ in a parenthesis over here or spread it out fully in this product vector. So, this is just a matter

of notation and I like to highlight this, because you use different sources of books on quantum mechanics, so you are going to find all of these notations.

(Refer Slide Time: 09:53)

First, we prove that:

$$m = m_1 + m_2$$

in the CGC

$$\langle m_1 m_2 | jm \rangle$$

2012-August PCD-STAP Unit 2 114

So, our proof is going to be based on a few factors and the first thing, we do is to prove that the Clebsch Gordan coefficient must have this m quantum number to be equal to the sum of these 2 m quantum numbers, that is a necessary condition, for the Clebsch Gordan coefficient to be non zero.

(Refer Slide Time: 10:16)

$$\vec{j} = \vec{j}_1 + \vec{j}_2 \quad \vec{j} \cdot \hat{u} = \vec{j}_1 \cdot \hat{u} + \vec{j}_2 \cdot \hat{u}$$

$$j_z = j_{1z} + j_{2z}$$

$$j_z |jm\rangle = (j_{1z} + j_{2z}) |jm\rangle$$

$$j_z |jm\rangle = (j_{1z} + j_{2z}) \left(\sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | jm \rangle \right) |jm\rangle$$

$$j_z |jm\rangle = (j_{1z} + j_{2z}) \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | jm \rangle$$

2012-August PCD-STAP Unit 2 115

Now, this proof is a very simple 1, it comes from the simple consideration or the fact that you simultaneously diagonalize j and j^2 and j_z or $j \cdot u$ in some direction. And you can therefore, construct an Eigen value equation of j_z and now over here in between you can sandwich, the unit operator that is one thing that, you know, theorists can do very freely, which is always insert a unit operator and resolve it, that is the resolution of unity, so you sandwich a unit operator. So, that you express, it as a linear superposition of base vectors in the uncoupled basis, this is a product of uncoupled vectors, uncoupled angular momentum Eigen states right, so this is one expression that, you have for the result j_z operating on $j m$.

(Refer Slide Time: 11:16)

$$j_z |jm\rangle = (j_{1z} + j_{2z}) \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle$$

$$j_z |jm\rangle = (j_{1z} + j_{2z}) \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |j_1 m_1 j_2 m_2\rangle \langle m_1 m_2 | jm\rangle$$

direct product

$$j_z |jm\rangle = (j_{1z} + j_{2z}) \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |j_1 m_1\rangle |j_2 m_2\rangle \langle m_1 m_2 | jm\rangle$$

$$j_z |jm\rangle = \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} (j_{1z} + j_{2z}) |j_1 m_1\rangle |j_2 m_2\rangle \langle m_1 m_2 | jm\rangle$$

2012-August PCD-STAP Unit 2 116

Now, you can expand these terms further, I have written the j_1 and j_2 more explicitly over here, this is a direct product of these 2 vectors, which is $j_1 m_1$ and $j_2 m_2$, so essentially, you have got these 2 operators $j_1 z$ and $j_2 z$ operating on this direct product. And there are 2 terms 1 coming from $j_1 z$ and the other coming from $j_2 z$, so you can get these 2 terms by explicitly carrying out the operation by $j_1 z$ plus $j_2 z$ on this product $j_1 m_1 j_2 m_2$.

(Refer Slide Time: 12:02)

$$\begin{aligned}
 j_z |jm\rangle &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} (j_{1z} + j_{2z}) |j_1 m_1\rangle |j_2 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 j_z |jm\rangle &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} j_{1z} |j_1 m_1\rangle |j_2 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 &\quad + \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} j_{2z} |j_1 m_1\rangle |j_2 m_2\rangle \langle m_1 m_2 | jm\rangle \left. \vphantom{\sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2}} \right\} \text{sum of two terms} \\
 j_z |jm\rangle &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} m_1 \hbar |j_1 m_1\rangle |j_2 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 &\quad + \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} m_2 \hbar |j_1 m_1\rangle |j_2 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 j_z |jm\rangle &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} (m_1 + m_2) \hbar |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle
 \end{aligned}$$

2012-August PCD-STIAP Unit 2 117

So, that result is quite simple, you will have $j_1 z$ operating on $j_1 m_1$ and $j_2 z$ operating on $j_2 m_2$, so these are the 2 terms, so you have written this entire double sum as a double sum of 2 terms. So, this is a fairly simple simplification of this expression, now what is $j_1 z$ operating on $j_1 m_1$, it is of course, $m_1 \hbar$ cross times $j_1 m_1$ right and $j_2 z$ are placed on $j_2 m_2$, which is this vector over here, it does nothing to $j_1 m_1$. Because, j_1 and j_2 are completely independent angular momentum that is what, I mean, when I said that the 2 individual spaces are completely disjoint, they have nothing in common.

So, $j_2 z$ will do nothing to $j_1 m_1$, but it will operate on $j_1 m_2$ giving you the Eigen value $m_2 \hbar$ cross and now you can, sum these 2 terms, because both are summations over the same base vectors $m_1 m_2$, 1 scaled by $m_1 \hbar$ cross and the other scaled by $m_2 \hbar$ cross. So, extract \hbar cross as common and you have got a factor m_1 plus m_2 times \hbar cross. So, this is a linear superposition of these base vectors, scaled by appropriate coefficients and these coefficients are \hbar cross times m_1 plus m_2 and do not forget the Clebsch Gordan coefficient, which is also there, so that is also involved in the scaling.

(Refer Slide Time: 13:52)

$$j_z |jm\rangle = \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} (m_1 + m_2) \hbar |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle$$

Also, $j_z |jm\rangle = m \hbar |jm\rangle$

$$j_z |jm\rangle = m \hbar \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle$$

$$j_z |jm\rangle = \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} m \hbar |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle$$

compare the coefficients in the linearly independent basis,

$\Rightarrow m = m_1 + m_2$
in the CGC $\langle m_1 m_2 | jm\rangle$

2012-August PCD-STAP Unit 2 118

So, that is the right hand side, left hand side is very simple to resolve, because j_z operating on $j m$ gives you an Eigen value equation and you can express this term once again by inserting a similar unit operator. So, that both on the left hand side and right hand side you have got linear superposition and basis as which are exactly the same then you can always extract the coefficients of corresponding terms that is the idea.

So, let us do that, so you have got j_z operating on $j m$, which gives you $m \hbar$ cross times this whole sum and now if you compare the coefficients, you have got 2 expressions on the right hand side, both being equal to the left hand side, which is j_z operating on $j m$. Both this term, as well as this term are expansions of the same basis sets, which is $m_1 m_2$ basis, they have got the same factor \hbar cross, which is common in both this Scalar comp the Clebsch Gordan coefficient is also common in both.

And now you have got $m_1 + m_2$ is 1 factor here, which must correspond to the factor m over here, because whenever you have expansions in linearly independent basis and if you have 2, such expansions, which are exactly equal to each other in the same orthonormal in the linearly independent basis, that the coefficients of the corresponding base vectors must be necessarily equal. So, that is a fundamental theorem that, we make use of and we find that m must be equal to $m_1 + m_2$ in every Clebsch Gordan coefficient, that is good.

(Refer Slide Time: 16:00)

$$\vec{j} = \vec{j}_1 + \vec{j}_2$$

$$m = -j, -j+1, \dots, j-1, j$$

We shall now establish the fact that:

$$j_{\min} = |j_1 - j_2| \quad j_{\max} = (j_1 + j_2)$$

i.e., $|j_1 - j_2| \leq j \leq (j_1 + j_2)$

2012-August PCD-STAP Unit 2 119

Now, we will proceed to establish, what the minimum and maximum values can be like, now this is what the result will turn out to be.

(Refer Slide Time: 16:14)

Consider the CGC

$$\langle (j_1 j_2) m_1 m_2 | (j_1 j_2) j m \rangle = \langle m_1 m_2 | j m \rangle$$

with $m_1 = m_1(\max) = j_1$
 $\& m = m(\max) = j$

i.e. $\langle (j_1 j_2) j_1 m_2 | (j_1 j_2) j j \rangle$

2012-August PCD-STAP Unit 2 120

And to do that, we now have a look at the Clebsch Gordan coefficient and just see, it is terms, so this is the full notation for the Clebsch Gordan coefficient, this is the brief notation in which, I have suppliers $j_1 j_2$. What we do know in this is m must be equal to $m_1 + m_2$ that is something, we have already established and we will use that result, now we use a particular Clebsch Gordan coefficient now. A particular 1, in which m_1

takes, it is maximum value and there is no ambiguity, there we know that the maximum value that m_1 can take is j_1 .

We also pick the maximum value of m , which must be j , there is no ambiguity about, this either, we know that the maximum value, m can take is j , we do not know, what is maximum value of j , but we do know what is a maximum value of m . The maximum value of j is what we are yet to determine, which we are about to determine, we do not know that as yet. But, the maximum value for each value of j is known that is m , so that is what we take, so now, we consider such a Clebsch Gordan coefficient, for which this m_1 is equal to j_1 , this m is equal to j . So, this is this $j m$ becomes j , because m is equal to j , m_2 is whatever it can be, but can only be m minus m_1 , so we do not put any constraint on m_2 externally, but it does have its own constraint that, it has to be m minus m_1 .

(Refer Slide Time: 18:13)

In our CGC: $m_2 = m - m_1 = j - j_1$

$$\langle (j_1 j_2) j_1 m_2 | (j_1 j_2) j j \rangle = \langle (j_1 j_2) j_1 j - j_1 | (j_1 j_2) j j \rangle$$

$$-j_2 \leq (j - j_1) \leq j_2 \quad -j_2 \leq m_2 \leq j_2$$

adding j_1

$$j_1 - j_2 \leq j \leq j_1 + j_2$$

assuming $j_1 > j_2$

j takes $2j_2 + 1$ values

2012-August PCD-STIAP Unit 2 121

So, we will exploit that, so m_2 can be only m minus m_1 , otherwise the Clebsch Gordan coefficient does not exist, so now, we know that this m_2 will be m minus m_1 , but m has taken its maximum value, which is j and m_1 has taken its maximum value, which is j_1 . So, this value m_2 is j minus j_1 , now that is good because this is a value, which m_2 takes, but you know, you already know that, the number of values that m_2 can take will be $2j_2 + 1$ and they will range from minus j_2 to plus j_2 , that is known.

So, this m_2 , which can belong to this range minus j_2 to plus j_2 , this m_2 being, what j_1 minus j_2 is you know have j_1 minus j_2 to fall in a certain range, which will have the lowest value, to which it can be equal, so this will be the minimum value, which is minus j_2 and the maximum value will be j_2 . Now, all you do is to add j_1 to every term in this inequality, so now, you have got j_1 minus j_2 here, you add j_1 , so j_1 minus j_2 plus j_1 will give you j_1 and now what you find is that j_1 belongs to this range.

Now, what is special about, 1 and 2, what we called as 1, we could have called as 2 and what we called as 2, we could have called as 1 right or you could begin with the other way around. So, any way what you essentially have is that, you have got a certain number of values, which m_2 can take and that number, we know very well must be $2j_2 + 1$ value. And these are the values that can be taken by whatever appears in the middle term of this inequality, which is j_1 right, the middle term can take $2j_2 + 1$ value. Likewise we have now found that j_1 can take $2j_2 + 1$ values, so remember this result and this is something that, we are going to use again in a very important, but simple step.

(Refer Slide Time: 20:52)

In our CGC: $m_2 = m - m_1 = j - j_1$

$$\langle (j_1 j_2) j_1 m_2 | (j_1 j_2) j j \rangle = \langle (j_1 j_2) j_1 j - j_1 | (j_1 j_2) j j \rangle$$

j takes $2j_2 + 1$ values

$$j_1 - j_2 \leq j \leq j_1 + j_2$$

likewise:

$$j_2 - j_1 \leq j \leq j_1 + j_2$$

For BOTH relations to hold:

$$|j_2 - j_1| \leq j \leq j_1 + j_2$$

2012-August PCD-STAP Unit 2 122

If we had called 1 as 2 and 2 as 1 or we could have begun first with the maximum value of m_2 and the maximum value of m and then find, what would be the maximum value of m_1 right, what are the values of m_1 that could be taken. We would get an exactly identical result that j_2 minus j_1 would be less than or equal to j less than or equal to $j_1 + j_2$

plus j_2 . So, these 2 expressions both are completely equivalent and both must be satisfied.

So, $j_1 - j_2$ must be less than or equal to j less than or equal to $j_1 + j_2$ and $j_2 - j_1$ should also be less than or equal to j less than or equal to $j_1 + j_2$, how can both be true, they can both be true, if and only, if you take the modulus of $j_2 - j_1$. So, your expression will have to have this constraint, your inequality will have to be that the minimum value will not be $j_1 - j_2$ or $j_2 - j_1$, it will depend on, which 1 is larger.

So, it has to be the modulus of this difference, because if one of them is larger than the other you will get into trouble and you must have both of these inequalities to hold, so you can satisfy both the inequalities by requiring that the modulus of this must be less than or equal to j less than or equal to $j_1 + j_2$.

(Refer Slide Time: 22:50)

So, this is a very nice result and it is called as triangular inequality, because if you look at the sides of a triangle A B and C then you have this inequality between the 3 sides. The modulus of the difference between these 2 sides will be less than or equal to the third side, which will be less than or equal to the sum of the other 2. So, that is the reason this is called as a triangle inequality and it is exactly the same kind of relation that, you get for the angular momentum, when you couple that, so we know, what is the range of j .

So, far so good, but we still have to get the dimensionality of the coupled space, we ant have anticipated the result, but we have not proved it, so we might as well prove it. So now that, we know that, the result holds good no matter, which is larger of the 2 and without any loss of generality.

(Refer Slide Time: 23:43)

Without any loss of generality,
we shall now assume:

$$j_1 \geq j_2$$

2012-August PCD STIAP Unit 2 124

Just for our discussion, we will assume that j_1 is greater than or equal to j_2 .

(Refer Slide Time: 23:50)

$-j_2 \leq m_2 \leq j_2$ m_2 can take $2j_2 + 1$ values

assuming $j_1 > j_2$

$j_1 - j_2 \leq j \leq j_1 + j_2$ j can take $2j_2 + 1$ values

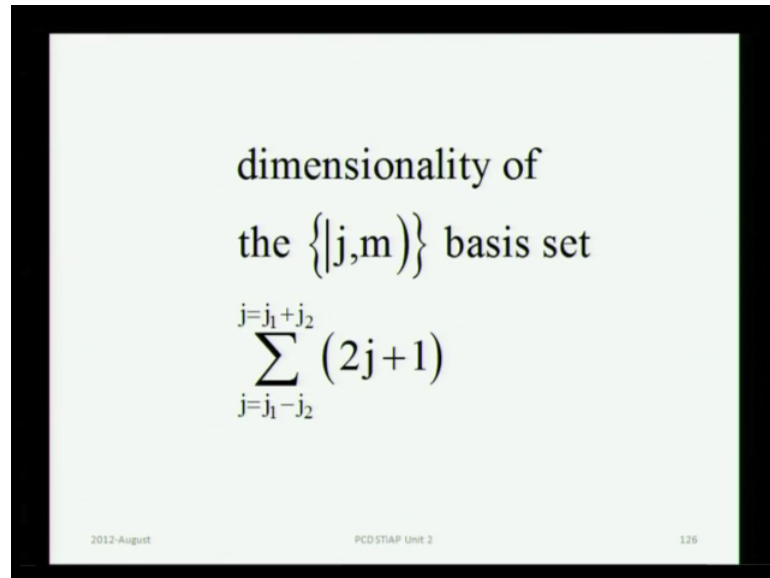

$\forall j, m$ has $2j + 1$ values in $|jm\rangle$

2012-August PCD STIAP Unit 2 125

We will use the result from here that m_2 can take $2j_2 + 1$ values and this is these are the number of values, which the j quantum number can take, so we know that this

quantum number j can take $2j + 1$ values. So, we will use this result and that is the reason this is highlighted in this yellow background, we are going to use it, in a very simple, but important step, so for every j m can take $2j + 1$ values, this is already known.

(Refer Slide Time: 24:34)

dimensionality of
the $\{|j, m\rangle\}$ basis set

$$\sum_{j=j_1-j_2}^{j=j_1+j_2} (2j+1)$$

2012-August PCD STAP Unit 2 126

So, what is the dimensionality of this space, it is $2j + 1$ for every j value m is going to take $2j + 1$ values, j will take all values from a minimum to a maximum the minimum is modulus of j_1 minus j_2 . But, we have assumed for our discussion that j_1 is larger than j_2 that is the reason, I have written it as j_1 minus j_2 to plus j_1 plus j_2 , there is no loss of generality in this, we have already established that, what does this sum add up to.

(Refer Slide Time: 25:17)

dimensionality of the $\{|j, m\rangle\}$ basis set

$$\sum_{j=j_1-j_2}^{j=j_1+j_2} (2j+1)$$

Assuming $j_1 \geq j_2$,
 $2j_2 + 1$ number of j values

Total number of states =

Total number of states =

$$2j_{\max} + 1$$

$$+ 2(j_{\max} - 1) + 1$$

$$+ 2(j_{\max} - 2) + 1$$

$$+ \dots$$

$$+ 2(j_{\min} + 1) + 1$$

$$+ 2j_{\min} + 1$$

Total number of states =

$$2(j_1 + j_2) + 1$$

$$+ 2((j_1 + j_2) - 1) + 1$$

$$+ 2((j_1 + j_2) - 2) + 1$$

$$+ \dots$$

$$+ 2(j_1 - j_2 + 1) + 1$$

$$+ 2(j_1 - j_2) + 1$$

(assuming $j_1 \geq j_2$)

2012-August PCD-STAP Unit 2 127

Now, let us carry out the sum explicitly and this sum can be carried out in a number of different ways and there are well known techniques, in you know, how you sum a series that, you can use to work out this sum. But, I will show you a very simple way of doing it, because it also gives you a little bit of physical insight into the whole story, you have the total number of states, which will be for each value of j , you know that, there will be $2j + 1$ values going from minimum to a maximum.

So, I have written all of these total number of states should be given by $2j_{\max} + 1$ then j_{\max} reduce by 1 plus 1 then reduced further by 1 plus 1, over here right and the lowest 1, lowest value of j will be j_{\min} and it will be $2j_{\min} + 1$. So, this is the total number of states right, now this is the total number of states and you can now write this, j_{\max} , we know as $j_1 + j_2$, j_{\min} is $j_1 - j_2$ right and in between the differences go in steps of 1.

So, the maximum value of written explicitly as $j_1 + j_2$ the minimum value, I have written explicitly as $j_1 - j_2$. So, it is the same box, which I have now written over here, which gives me the total number of states and I am going to bring this box in the right hand side to the next slide.

(Refer Slide Time: 26:58)

dimensionality of the $\{|j, m\rangle\}$ basis set: $\sum_{j=j_2-j_1}^{j=j_2+j_1} (2j+1)$

<p>Total number of states =</p> $2(j_1 + j_2) + 1$ $+ 2((j_1 + j_2) - 1) + 1$ $+ 2((j_1 + j_2) - 2) + 1$ <p style="text-align: center;">+.....</p> $+ 2(j_1 - j_2 + 1) + 1$ $+ 2(j_1 - j_2) + 1$ <p style="text-align: center;">(assuming $j_1 \geq j_2$)</p>	<p style="text-align: center;">=</p> $2j_1 + 1 + 2j_2$ $+ 2j_1 + 1 + 2j_2 - 2$ $+ 2j_1 + 1 + 2j_2 - 4$ <p style="text-align: center;">+.....</p> $+ 2j_1 + 1 - 2j_2 + 4$ $+ 2j_1 + 1 - 2j_2 + 2$ $+ 2j_1 + 1 - 2j_2$	<p style="text-align: center;">=</p> $2j_1 + 1$ $+ 2j_1 + 1$ $+ 2j_1 + 1$ <p style="text-align: center;">+.....</p> $+ 2j_1 + 1$ $+ 2j_1 + 1$ $+ 2j_1 + 1$
--	--	--

2012-August PCD-STAP Unit 2 128

And continue the analysis, so this is the same box, we have got $2j_{\text{max}} + 1$, which is now $2j_1 + 1 + j_2 + 1$, the slowest 1 was $2j_{\text{min}} + 1$, which without any loss of generality is $2j_1 - j_2 + 1$ right. And now let us analyze this further, because you expand this, this is $2j_1 + 1 + 2j_2 + 1$, so I have written this as $2j_1 + 1 + 2j_2$, this is you have $2j_1$ again $2j_2$ then you have 2 into minus 1 , which will give you minus 2 , so that minus 2 comes here.

So, this entire expression is completely equivalent to this row over here, like wise if you look at the next one, in which this number is reduced by 1 , so this becomes minus 2 and now you have $2j_1 + 1 + 2j_2$. So, you have $2j_1$ here, $2j_2$ is here you have 2 into minus 2 , which is minus 4 minus 4 comes here and then you have got this 1 , which is sitting over here, so all the terms are taken care of.

And you see that every term or set of terms is completely equivalent to the set of terms in the next box, the lowest 1 is $2j_1 - j_2 + 1$, which is $2j_1 - j_2 + 1$, this plus 1 comes here and this 2 , it is already there right, this is 1 , this is 1 . So, this is $2j_1$ and this plus 1 is coming from here and this minus $2j_2$ is coming from this 2 into minus j_2 , so this is the corresponding term good. Now, let us have a look at this, this $2j_2 + 2j_2$ cancels this minus $2j_2$.

They are all in the same box, they are all adding to each other, but this one comes with a plus sign, this one comes with a minus sign, so they kill each other then the $2j_2$ minus

2, this one comes with a plus sign and a minus sign over here, these are with opposite signs over. So, these 2 terms kill each other and likewise, this $2j_2 - 4$ will cancel minus $2j_2 + 4$ and they will all cancel out likewise.

Every term and what you are going to be left with is just $2j_1 + 1$ coming from here, $2j_1 + 1$ coming from here, $2j_1 + 1$ from here $2j_1 + 1$ coming from here and all you will be doing is to add up $2j_1 + 1$ to $2j_1 + 1$ plus $2j_1 + 1$ plus. And how many times, you do it $2j_2 + 1$ times, you will do it exactly $2j_2 + 1$ times, because those are the values that j can take, so the result is that when you carry out this series summation, it turns out to be a product of $2j_1 + 1$ times $2j_2 + 1$.

So, it is a very simple proof and you know that the final dimensionality of the space turns out to be, what we expect it to be and it is not a mystery and it is not coming just from our expectation from your intuitive expectation that, it has to have the same dimensionality. But, you can actually show it by carrying out the summations explicitly and looking at the dimensionality of the space.

(Refer Slide Time: 30:48)

Assuming $j_1 > j_2$,
 $2j_2 + 1$ number of j values

$$\sum_{j=j_2-j_1}^{j=j_2+j_1} (2j+1) = (2j_1+1)(2j_2+1)$$

dimensionality of the composite space

2012-August PCD-STIAP Unit 2 131

So, now we have got the final expression, for the dimensionality of the space.

(Refer Slide Time: 30:54)

Recursion relations for CGCs

$$\vec{J} = \vec{J}_1 + \vec{J}_2 \Rightarrow J_{\pm} = J_{1\pm} + J_{2\pm}$$

Consider: $J_{+} = J_{1+} + J_{2+}$

$$J_{+}|jm\rangle = (J_{1+} + J_{2+}) \left(\sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | jm \rangle \right)$$

i.e., $\mathcal{U}_+ = \hbar \sqrt{j(j+1) - m(m+1)} |j, m+1\rangle$

$$\mathcal{U}_+ = \hbar \sqrt{j(j+1) - m(m+1)} \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | j, m+1\rangle$$

2012-August FCD-STAP Unit 2 132

And we will proceed to work with the Clebsch Gordan coefficients and I will develop the recursion relations for the Clebsch Gordan coefficients, because it is very nice that, you can get all the Clebsch Gordan coefficients, just from one number. And you begin with that number, which happens to be 1, which all of us know, what it is and from that, you can get every other coefficient, but we have to see, how and why this is true.

So, let us look at the summation of the angular momenta and this guarantees that, the if you add the corresponding step up and step down ladder operators, they will give you the step up and step down, for the coupled angular momentum. And we consider the 1 with plus sign, there is a similar expression for the minus sign, for the step down operator as the well, but I will consider the step up operator.

And operate on the coupled angular momentum by the step up operator, on the right hand side, I decompose the coupled step up operator in terms of these components j_1 plus and j_2 plus and insert the resolution of the unit operator. So, left hand side we know from, what we have done earlier is given by this square root term, we have done this number of times already.

(Refer Slide Time: 32:47)

$$\begin{aligned}
 j_+ |jm\rangle &= (j_{1+} + j_{2+}) \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 \text{rhs} &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} (j_{1+} + j_{2+}) |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 \text{rhs} &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} (j_{1+} + j_{2+}) |j_1 m_1 j_2 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 \text{rhs} &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} (j_{1+} + j_{2+}) |j_1 m_1\rangle |j_2 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 \text{rhs} &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} [j_{1+} |j_1 m_1\rangle] |j_2 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 &\quad + \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} [j_{2+} |j_2 m_2\rangle] |j_1 m_1\rangle \langle m_1 m_2 | jm\rangle
 \end{aligned}$$

So, this is your left hand side and you can again insert a unit operator here and then take this coefficient inside, so we know look at the right hand side, now the right hand side is obtained from the operation by a sum of 2 operators. So, you can separate the 2 terms by operating by these 2 terms individually on this and j_1 plus will operate on the m_1 pod and j_2 plus will operate on the m_2 pod, because the 2 vector spaces are completely disjointed.

So, this product of the uncoupled vectors, I have written explicitly as a direct product of these 2 vectors, we know what a direct product is and now, we will let j_1 plus operate on $j_1 m_1$ and j_2 plus operate on $j_2 m_2$ and we know, that these are step up operators. So, it will raise the corresponding Azimuthal quantum number respectively by 1, so j_1 plus will operate on $j_1 m_1$, j_2 plus will operate on $j_2 m_2$, over here $j_2 m_2$, simply comes out as a multiplier whereas, over here $j_1 m_1$ comes out as a multiplier. But, of course, there is a residual multiplier, which is coming from the Clebsch Gordan coefficients, so that will be carried forward.

(Refer Slide Time: 34:18)

$$\begin{aligned}
 j_+ |jm\rangle &= (j_{1+} + j_{2+}) \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 \text{rhs} &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} [j_{1+} |j_1 m_1\rangle] |j_2 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 &\quad + \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} [j_{2+} |j_2 m_2\rangle] |j_1 m_1\rangle \langle m_1 m_2 | jm\rangle \\
 \text{rhs} &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \sqrt{j_1(j_1+1)-m_1(m_1+1)} |j_1 m_1+1\rangle |j_2 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 &\quad + \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \sqrt{j_2(j_2+1)-m_2(m_2+1)} |j_1 m_1\rangle |j_2 m_2+1\rangle \langle m_1 m_2 | jm\rangle \\
 \text{rhs} &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \sqrt{j_1(j_1+1)-m_1(m_1+1)} |m_1+1 m_2\rangle \langle m_1 m_2 | jm\rangle \\
 &\quad + \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \sqrt{j_2(j_2+1)-m_2(m_2+1)} |m_1 m_2+1\rangle \langle m_1 m_2 | jm\rangle
 \end{aligned}$$

So, we have this right hand side and j_1 plus when it operates on $j_1 m_1$ will raise the m_1 index to m_1 plus 1 and then it will scale the resultant vector by this \hbar cross times, this square root factor, which we have handled earlier. You are going to have the same thing happen to the second term, in which you have the j_2 plus operate on the $j_2 m_2$, so the m_2 index will go up by 1, so here you have the m_2 index go up to m_2 plus 1. And then you have the \hbar cross sign, the square root factor and you do have the Clebsch Gordan coefficient factor.

Now, this is rather interesting both of these are summations in the $m_1 m_2$ basis, but you cannot combine them, because in one the indexes m_1 plus 1 m_2 and in the second term here, this index is m_2 plus 1. So, you will like to combine these 2 terms and you can certainly do that, because both of them are complete summations here m_1 goes from minus j_1 to plus j_1 , m_2 goes from minus j_2 to plus j_2 same thing happens in the second term that m_1 goes from minus j_1 to plus j_1 and m_2 goes from minus j_2 to plus j_2 .

So, both are summations in the complete set of bases, it is going to pick every term, so instead of counting from here and then take the next term and then take this term and then go all over and come back, you can begin counting from here, take the next term and come back, I will pick all the terms in the complete set of bases right. So, it is like counting the number of students in the class and I can begin with Arati and go around or

I can begin over here and then go around. So, it does not matter, where you begin the counting, it is exactly that.

(Refer Slide Time: 36:38)

$$\begin{aligned}
 L_- &= \hbar \sqrt{j(j+1) - m(m+1)} \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1, m_2\rangle \langle m_1, m_2 | j, m+1 \rangle \\
 L_- &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \sqrt{j_1(j_1+1) - m_1(m_1+1)} |m_1+1, m_2\rangle \langle m_1, m_2 | j, m \rangle \\
 &\quad + \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \sqrt{j_2(j_2+1) - m_2(m_2+1)} |m_1, m_2+1\rangle \langle m_1, m_2 | j, m \rangle \\
 L_- &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \sqrt{j_1(j_1+1) - (m_1-1)m_1} |m_1-1, m_2\rangle \langle m_1-1, m_2 | j, m \rangle \\
 &\quad + \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \sqrt{j_2(j_2+1) - (m_2-1)m_2} |m_1, m_2-1\rangle \langle m_1, m_2-1 | j, m \rangle \\
 L_- &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \left\{ \sqrt{j_1(j_1+1) - (m_1-1)m_1} \langle m_1-1, m_2 | j, m \rangle \right. \\
 &\quad \left. + \sqrt{j_2(j_2+1) - (m_2-1)m_2} \langle m_1, m_2-1 | j, m \rangle \right\} |m_1, m_2\rangle
 \end{aligned}$$

2012-August PCD-STIAP Unit 2 135

So, let us do that by shifting the index, I can get both the terms expressed as superposition over the same base vectors, but the indices must be shifted, because here the index is m_1, m_2 , in this first term, you have m_1 plus on in the second term, you have m_2 plus 1. So, if you want to make the summations correspond to each other, you must drop this index m_1 plus on to m_1 , but then you must drop every m_1 by 1. So, this m_1 must be reduced by 1, this will become m_1 minus 1, this m_1 will also become m_1 minus 1, this m_1 plus 1 must be dropped by 1, so it must become m_1 .

So, by dropping that index that quantum number by unity, you make all the terms, such that the linear superposition is over the dummy index m_2 rather than, m_2 plus 1 or m_1 plus 1. And it does not matter, whether the dummy index is m_1 plus 1 or m_1 itself, it is exactly like counting the number of students in the class, it does not matter, where you begin the counting, you can count with the next student or the 1 after him or the 1 after him and then go back count everybody and then go back to the previous 1.

So, that is exactly, what you are doing and now having shifted the indices, but in shifting must be done in a very consistent manner, so if you change this index from m_1 plus 1 to m_1 , then in the corresponding term, every m_1 must be dropped by 1. You do the same in the second term and now you have got expansions in both the terms, which are in the

same running index as such, which is $m_1 - 1$ m_2 , but the coefficients of course, are different and you can combine these coefficients now.

So, you have now combined the coefficients \hbar cross comes out as a common factor, the 2 remaining co factors are combined together, which includes the square root term and the corresponding Clebsch Gordan coefficient, this one has got $m_1 - 1$ minus 1 over here, this 1 has got m_2 minus 1 here. Because, how did we get that, because of shifting the indices in a consistent manner, so now we have got the right hand side expressed as a linear superposition of base vectors $m_1 - 1$ m_2 .

(Refer Slide Time: 39:24)

$$\text{lhs} = \hbar \sqrt{j(j+1) - m(m+1)} \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 \ m_2\rangle \langle m_1 m_2 | j \ m+1\rangle$$

$$\text{rhs} = \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \left\{ \sqrt{j_1(j_1+1) - (m_1-1)(m_1)} \langle m_1-1 \ m_2 | j \ m \rangle + \sqrt{j_2(j_2+1) - (m_2-1)(m_2)} \langle m_1 \ m_2-1 | j \ m \rangle \right\} |m_1 \ m_2\rangle$$

Comparing respective coefficients

$$\sqrt{j(j+1) - m(m+1)} \langle m_1 m_2 | j \ m+1\rangle = \sqrt{j_1(j_1+1) - (m_1-1)(m_1)} \langle m_1-1 \ m_2 | j \ m \rangle + \sqrt{j_2(j_2+1) - (m_2-1)(m_2)} \langle m_1 \ m_2-1 | j \ m \rangle$$

Recursion relation for the CGC

2012-August PCD STIAP Unit 2 136

Left hand side is also expressible as a linear superposition of the same base vectors $m_1 - 1$ m_2 and now you can compare the corresponding coefficients \hbar cross cancels. And now you have got a relation, which connects this Clebsch Gordan coefficient with this and this, in which the indices are shifted, now this is the recursion relation.

You get it means, that Clebsch Gordan coefficients are not completely independent of each other, they have some relationship with the neighboring Clebsch Gordan coefficients. And you can find, what these exact values are because there is another recursion relation, that you will get by using the step down operator.

(Refer Slide Time: 40:25)

You get another recursion relation, beginning with j_-

$$j_- |jm\rangle = (j_- + j_{2-}) \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle$$

and following a similar procedure

2012-August PCD STAP Unit 2 137

And using exactly the same procedure, so there is more help available than, what we obtained in the previous run the other relation is the recursion relation, that you will get, which I leave as homework, it is the same procedure, you can do it quite easily. So, this is these are the 2 recursion relation that, you get.

(Refer Slide Time: 40:47)

You get another recursion relation, beginning with j_-

$$j_- |jm\rangle = (j_- + j_{2-}) \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle$$

and following a similar procedure

2012-August PCD STAP Unit 2 137

And I have combined the 2 recursion relations by writing, this expression inclusive of a plus and minus sign over here, and there are corresponding plus and minus signs, there is a minus and plus signs. So, you get the top signs to correspond to each other lower signs

to correspond to each other and that is where the 2 relations are written together in this expression.

So, these are the recursion relations for the Clebsch Gordan coefficients, you already know that, the term under the square root can be written, as a product of 2 factors that is just a matter of notation again and these recursion relations are extremely useful in getting the Clebsch Gordan coefficients and doing angular momentum algebra. So, you can write them, in terms in 1 or the other notation and different books make use of you know different kinds of notations, that is just a matter of detail.

(Refer Slide Time: 41:41)

So, this is the summary of what we have got, so far and we established the triangle inequality, we know exactly, what the angular momentum j can be, it can take only these values, it can take a minimum value, which can be the modulus of j_1 minus j_2 or modulus of j_2 minus j_1 , however, you would like to say that. And this is called as a triangle inequality, you also learned today that, the dimensionality of the basis must be $2j_1 + 1$ times $2j_2 + 1$, as we expected already. From our reasoning that, it is the same product space, which is being expressed in a different basis set, which is the Eigen basis of the coupled angular momentum.

So, the other thing that, we did today was to obtain the recursion relations between the Clebsch Gordan coefficients and these are very important steps or important elements of the angular momentum algebra, you are going to find them very useful. And we will

continue to use the wiggler d matrices, which are quite important, but now we are much better equipped to do that. So, if there are any questions, I will be happy to take otherwise, I will stop here, today and we will continue from this point, in the next class, questions.

$$\begin{aligned}
 \text{lhs} &= \hbar \sqrt{j(j+1) - m(m+1)} \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} |m_1 \ m_2\rangle \langle m_1 m_2 | j \ m+1 \rangle \\
 \text{rhs} &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \sqrt{j_1(j_1+1) - m_1(m_1+1)} |m_1+1 \ m_2\rangle \langle m_1 m_2 | j m \rangle \\
 &\quad + \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \sqrt{j_2(j_2+1) - m_2(m_2+1)} |m_1 \ m_2+1\rangle \langle m_1 m_2 | j m \rangle \\
 \text{rhs} &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \sqrt{j_1(j_1+1) - (m_1-1)(m_1)} |m_1 \ m_2\rangle \langle m_1-1 \ m_2 | j m \rangle \\
 &\quad + \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \sqrt{j_2(j_2+1) - (m_2-1)(m_2)} |m_1 \ m_2\rangle \langle m_1 \ m_2-1 | j m \rangle \\
 \text{rhs} &= \sum_{m_1=-j_1}^{j_1} \sum_{m_2=-j_2}^{j_2} \hbar \left\{ \sqrt{j_1(j_1+1) - (m_1-1)(m_1)} \langle m_1-1 \ m_2 | j m \rangle \right. \\
 &\quad \left. + \sqrt{j_2(j_2+1) - (m_2-1)(m_2)} \langle m_1 \ m_2-1 | j m \rangle \right\} |m_1 \ m_2\rangle
 \end{aligned}$$

2012-August PCD-STIAP Unit 2 135

Here this is the part of the expression, but the sums is here these 2 sums are completely independent to each other, these are 2 separate terms, what happens in the first term, does not affect anything in the second term and vice versa. So, in the first term, we are dropping the m 1 index and we do it consistently for everything in the first term, in the second term, we drop the m 2 index, but then we do not touch the first the other index, which is m 1, we have to do it independently.

It is not that, we can we have no choice, we have to do it independently, because the 2 terms are completely independent to each other, you do the counting the counting is within each term. You have a double sum, you decompose this double sum into these 2 terms right. So, this what I have over here, if you are able to see the locus of this arrow, what is inside this is 1 term, this is what I call as t 1 first term, this is now the second term, which is t 2.

And that summation in t_1 has a value, which is quite independent of what is happening in t_2 , you have decomposed it and then each term has its own significance, it has its own merit, it has its own strength and the indices have got an impact within that term. A dummy sum in term 1, a dummy index in term 1, does nothing to a dummy index in term 2, but a dummy index in term 1, has to be handled consistently within the term 1.

And you must do the same with the second term that, whatever is the dummy index, if you shift the dummy index, within the second term then within the second all the corresponding indices must be shifted consistently right, any other question. But a good point it is need to know that, because you know, you will be doing fairly complex algebra with angular momentum terms and then it is important to do this carefully, because it is very easy to make a mistake, let me assure you that.

It does not matter, the summation symbol is a dummy symbol, all it is telling us is that go pick every term, you can call, you can define $m_1 + 1$ as m_1' and then have a dummy index m_1' equal to $m_1 + 1$, you can add 1 more step, if you like, it is not going to change the result. All you have to remember is that, it is a dummy index, which must pick every value in the range of m_1 and every value in the range of m_1 is minus j_1 to plus j_1 .

And the example of counting the number of students in this class, I really a very appropriate 1, because you have to count every single term and it absolutely does not matter, where you begin the counting from, I can begin counting with Arati or begin counting with Ankur although cosmic may complain, why not me. So, we can start counting from cosmic and then go back till there right, but you are going to get the total number of students will be exactly the same. So, you are picking every term in the basis, any other question.

So thank you very much.
