Lorentz transformation
$$\psi(x) \rightarrow e^{-\frac{i}{4}\omega_{\mu\nu}\Sigma^{\mu\nu}}\psi(x)$$

where $\Sigma^{\mu\nu} = \frac{i}{2}[\gamma^\mu, \gamma^\nu]$
 γ^μ : Dirac matrices
$$\{\gamma^\mu, \gamma^\nu\} = 2\eta^{\mu\nu}$$

So, in the last lecture we have introduced the Dirac spinor, ψ and then I have shown how it transforms under Lorentz transformation. So, under Lorentz transformation the Dirac spinor goes like ψ of x goes to e to the power minus over 4 $\omega_{\mu\nu}\Sigma^{\mu\nu}$ acting on ψ of x . Where $\Sigma^{\mu\nu}$ is given by i over 2 commutator of $\gamma^\mu\gamma^\nu$, where the $\gamma^\mu\gamma^\nu$ are the Dirac matrices. They are a set of 4 by 4 matrices, which satisfy the anti-commutation relation, $\gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = 2\eta^{\mu\nu}$, then we have seen that in one particular representation known as chiral representation.

(Refer Slide Time: 1:44)

This Dirac matrix, this Dirac spinor can be written as ψ_L ψ_R into subdivided left handed and right handed components. And the Dirac matrices in the chiral representation γ^0 given by $\begin{pmatrix} 0 & -I \\ -I & 0 \end{pmatrix}$ and γ^i equal to $\begin{pmatrix} 0 & \sigma^i \\ -\sigma^i & 0 \end{pmatrix}$. So, these are Dirac matrices however, we need not have this representation, any representation, any set of 4 by 4 matrices will satisfy these anti-commutation relation, will be good enough to represent the Dirac gamma matrices, the Dirac spinors.

Then what we saw is that we can try to construct various invariants from the Dirac spinor, one of them we have seen is if we define $\bar{\psi}$ equal to $\psi^\dagger \gamma^0$, then $\bar{\psi} \psi$ is actually Lorentz invariant. Then we were discussing Lorentz transference property of this subject $\bar{\psi} \gamma^\mu \psi$. So, let us see how this subject transforms under Lorentz transformation. This transforms like $\bar{\psi}$ goes to $\bar{\psi} S(\lambda)^{-1}$ and then, γ^μ and then ψ goes to $S(\lambda) \psi(x)$. So, this is how it transfers.

(Refer Slide Time: 3:52)

$$\begin{aligned}
 S^{-1}(\lambda) \gamma^\mu S(\lambda) &= \Lambda^\mu_{\nu} \gamma^\nu \\
 &= \left(1 + \frac{i}{4} \omega_{\alpha\beta} \Sigma^{\alpha\beta} + \dots \right) \gamma^\mu \left(1 - \frac{i}{4} \omega_{\rho\sigma} \Sigma^{\rho\sigma} + \dots \right) \\
 &= \gamma^\mu + \frac{i}{4} \omega_{\alpha\beta} \Sigma^{\alpha\beta} \gamma^\mu - \frac{i}{4} \omega_{\rho\sigma} \gamma^\mu \Sigma^{\rho\sigma} + \dots \\
 &= \gamma^\mu + \frac{i}{4} \omega_{\alpha\beta} [\Sigma^{\alpha\beta}, \gamma^\mu] + \dots \\
 &= \left(\delta^\mu_{\nu} + \omega^\mu_{\nu} + \dots \right) \gamma^\nu \\
 &= \Lambda^\mu_{\nu} \gamma^\nu
 \end{aligned}$$

So, what we need to do is, we need to know what is this object $S^{-1} \lambda \gamma^\mu S$ of λ , we can do an infinitesimal transformation where, this is given by two order $\omega_{\mu\nu}$. This is $1 - i$ over $4 \omega_{\mu\nu} \sigma_{\mu\nu}$, then let me write it as $\alpha\beta$, $\alpha\beta \gamma^\mu$ and $1 - i$ over $4 \omega_{\rho\sigma} \sigma_{\rho\sigma}$. So, to order ω this looks like $1 - i$ over $4 \omega_{\alpha\beta} \sigma_{\alpha\beta} \gamma^\mu$.

So, this is a γ^μ to the 0th order and then, this will be plus because we are considering S^{-1} . So, there is a plus sign here and then you have finally, minus i over $4 \omega_{\alpha\beta} \gamma^\mu \sigma_{\alpha\beta}$ and all other terms. So, this is nothing but γ^μ plus i over 4 plus $\omega_{\alpha\beta}$ and the commutator of $\sigma_{\alpha\beta}$ and γ^μ and all other terms.

And in the last lecture we have evaluated the commutator of $\sigma_{\alpha\beta}$ and γ^μ and if you substitute it here, then what you see is you have γ^μ i over 4 . So, finally all the factors will cancel and what you will get is, $\delta^\mu_{\nu} + \omega^\mu_{\nu}$ plus γ^ν . So, this is simply given by $\Lambda^\mu_{\nu} \gamma^\nu$. So, this object $S^{-1} \gamma^\mu S$ is nothing but when you make a finite transformation, this will go like $\Lambda^\mu_{\nu} \gamma^\nu$.

(Refer Slide Time: 6:56)

So, therefore, this object here $\bar{\psi} \gamma^\mu \psi$ under a Lorentz transformation, goes like a vector because, this quantity, this is nothing but $\Lambda^\mu_\nu \bar{\psi} \gamma^\nu \psi$. So, therefore this is a vector under Lorentz transformation. Similarly, we can construct a tensors and pseudo-scalars and pseudo-vectors and so on, under Lorentz transformation. What we are interested is, we are interested to construct a Lorentz invariant Lagrangian density. So, this would involve ψ and its derivatives.

(Refer Slide Time: 7:49)

You can try to construct a Lorentz invariant Lagrangian density, which is quadratic in $\partial_\mu \psi$ but it turns out that any such Lagrangian, this is quadratic in $\partial_\mu \psi$ gives you various unphysical features. For example, the energy has no lower bound and so on however, luckily we have a Lagrangian density which is first order in $\partial_\mu \psi$, which is Lorentz invariant. So, let us try to construct a term which is first order in $\partial_\mu \psi$, which is Lorentz invariant, to do that consider this term $\bar{\psi} \gamma_\mu \partial_\mu \psi$.

This quantity here, as you know $\bar{\psi}$ this ∂_μ is not there, then this would have transformed like a vector but we wanted to have one derivative of field ψ . So, we have inserted this $\partial_\mu \psi$ here and then we can show that this quantity over here is invariant under Lorentz transformation. While this $\bar{\psi}$ goes to $\bar{\psi}' S^{-1}$ and then you have γ_μ and ∂_μ under Lorentz transformation goes to, ∂_μ is $\partial / \partial x^\mu$ and under Lorentz transformation this goes to $\partial x^\mu / \partial x'^\mu$.

So, this quantity is $S^{-1} \gamma_\mu S \partial_\mu \psi$. So, you have $S^{-1} \gamma_\mu S$ but S does not depend on space time. So, I can just pull it out, what I get is $\bar{\psi}' S^{-1} \gamma_\mu S \partial_\mu \psi$ and $S^{-1} \gamma_\mu S$ is a number. So, again the components of γ_μ are numbers so, again I can pull it out.

So, I have $S^{-1} \gamma_\mu S \partial_\mu \psi$. This quantity is again we have computed, what it is $\partial_\mu \psi$ so, I can substitute this here, then what I will get is $\bar{\psi}' \gamma_\mu \partial_\mu \psi$ and γ_μ is $\gamma_\alpha \delta^\alpha_\mu$. And finally, this is simply $\bar{\psi}' \gamma_\alpha \partial_\alpha \psi$. So, this quantity is Lorentz invariant so, you can have Lagrangian density for a massive spin of field.

(Refer Slide Time: 12:06)

$$\mathcal{L}_{Dirac} = \bar{\psi} (i \gamma^\mu \partial_\mu - m) \psi$$
$$(i \gamma^\mu \partial_\mu - m) \psi = 0$$

Dirac equation.

$$\pi_\psi = \frac{\partial \mathcal{L}}{\partial \dot{\psi}} = i \bar{\psi} \gamma^0$$
$$\pi_{\bar{\psi}} = 0$$

And the Lagrangian density is given by 1 Dirac, the 1 Dirac Lagrangian is $\bar{\psi} i \gamma^\mu \partial_\mu \psi - m \bar{\psi} \psi$. I have inserted a factor of i to make the Hamiltonian Hermitian, which we will soon see, how the Hamiltonian density is Hermitian, it will not be Hermitian, if there is no i here. So, we will take this Lagrangian density for the Dirac field and then, we will quantize the system. As usual, before quantizing this we have to first study the plain wave solutions for this field here.

Let us do various things for example, let us try to construct the Hamiltonian density and so that, the Hamiltonian is Hermitian and let us look for the plain wave solutions for the equation of motion. What is the equation of motion? The equation of motion is given by $i \gamma^\mu \partial_\mu \psi - m \psi = 0$ and this is known as the Dirac equation. And we would like to study the plain wave solution to the Dirac equation, which we will do in a moment before that, let us try to construct the Hamiltonian. So, the conjugate momentum to the field ψ is given by $\pi_\psi = \frac{\partial \mathcal{L}}{\partial \dot{\psi}} = i \bar{\psi} \gamma^0$ and this is nothing but i times $\bar{\psi} \gamma^0$, what is $\pi_{\bar{\psi}}$? 0, right.

(Refer Slide Time: 14:40)

So, let us try to construct the Hamiltonian density, it is given by $i\bar{\psi}\gamma^0\partial_0\psi$ minus \mathcal{L} . So, the Hamiltonian equals to H is given by this and if you substitute for the Lagrangian density then, this is $i\bar{\psi}\gamma^0\partial_0\psi$ minus $i\bar{\psi}\gamma^i\partial_i\psi$ plus $m\bar{\psi}\psi$. So, this is simply $-i\bar{\psi}\gamma^i\partial_i\psi$ plus $m\bar{\psi}\psi$.

Now, you know why I have inserted this symbol, this effector of i here? Because, $i\partial_i$ this is Hermitian operator. So, you can write, the second term is obviously Hermitian because, $\bar{\psi}\psi$ is Hermitian, $\bar{\psi}\psi$ is $\psi^\dagger\gamma^0\psi$, which is the Hermitian conjugate of this quantity is equal to itself because, γ^0 is Hermitian. And then you have $\psi^\dagger\psi$ on the both sides, but in the first term you have ψ^\dagger and $\gamma^0\gamma^i$ and $-i\partial_i\psi$ and this operator inside will be Hermitian if this is Hermitian so, let us. So, let us just take Hermitian conjugate of that.

(Refer Slide Time: 17:12)

$$\begin{aligned}
 &+i\partial_i \psi^\dagger \gamma^i \gamma^0 \psi \\
 &= i\partial_i \psi^\dagger \gamma^0 \gamma^i \gamma^0 \psi \\
 &= i\partial_i \bar{\psi} \gamma^i \psi \\
 &= -i\bar{\psi} \gamma^i \partial_i \psi + i\partial_i (\bar{\psi} \gamma^i \psi)
 \end{aligned}$$

It is just minus i will give you plus i del i psi dagger and then gamma i dagger gamma 0 psi. And what is gamma i dagger? gamma i dagger is i del i psi dagger gamma 0 gamma i gamma 0 gamma 0 psi, gamma 0 square is 1. So, this is simply i del i psi bar gamma i psi and then, this will be up to a total derivative. This is just minus i psi bar gamma i del i plus i del i psi bar gamma i psi.

(Refer Slide Time: 18:17)

$$\begin{aligned}
 J^\mu &= \bar{\psi} \gamma^\mu \psi \\
 \partial_\mu J^\mu &= 0 \\
 \vec{P} &= -i \int d^3x \psi^\dagger \vec{\nabla} \psi \\
 Q &= \int d^3x \psi^\dagger \psi
 \end{aligned}$$

There is u and invariance and then, you can show that there exists a conjugate mu, which is given by psi bar gamma mu psi and that mu is equal to 0. I will not do this for you and

you can construct various quantities like the momentum and so on. You can construct the energy momentum operator and then you will have the momentum which is given by minus $i \nabla \cdot x$ psi dagger ((Refer time: 19:11)) psi. The total charge Q will be $\int d^3x \psi^\dagger \psi$ and so on. What we will be studying is, we will consider plane wave solutions to the Dirac equations so, let us do that. As usual, we will consider both positive frequency as well as negative frequency modes.

(Refer Slide Time: 20:00)

The positive frequency modes, I will denote them by psi plus of x, which will go like u of p e to the power of minus $i p \cdot x$. And the negative frequency modes, I will denote them as psi minus of x, which will go like v of p e to the power of $i p \cdot x$. I will substitute these two forms and then I will see what, then we will discuss, what are the expressions for these spinors u of p and v of p ?

So, let us consider the Dirac equation, the Dirac equation is given by $i \gamma^\mu \partial_\mu \psi - m \psi = 0$. For positive frequency modes, this will be $\psi^+ = 0$ and this simply implies $i \gamma^\mu \partial_\mu \psi^+ - m \psi^+ = 0$. This simply implies that $\gamma^\mu p_\mu - m$ acting on u of p equal to 0. Contraction of γ^μ with various operators will appear quite frequently, I will use the symbol slash to denote contraction with γ^μ .

For example, I will denote \not{p} for $\gamma^\mu p_\mu$ and so on. And $\not{\partial}$ for $\gamma^\mu \partial_\mu$, whenever I use a slash it is just $\gamma^\mu \partial_\mu$ and so on. So,

this, this I can write it as $\not{p} + m$ acting on u of p equal to 0. By solving this equation, we will find the most general expression for u of p . Similarly, if you look for the negative frequency modes, then, you will get an equation for v of p .

(Refer Slide Time: 22:51)

I will summarize these two equations $\not{p} - m$ u of p equal to 0, $\not{p} + m$ v of p equal to 0. These are the two equations separated by u of p and v of p , as you can see directly from the Dirac equation or in other words, these are the Dirac equations for the spinors u of p and v of p . We want to solve these two equations, to solve that, note that if we consider massive fields, then we can go to the rest frame. Where, the momentum, the for momentum p is simply m and 0 in the rest frame because, there is free momentum is 0 in the rest frame. We already know that, these equations are co-variants under Lorentz transformation.

So, you can solve it in the rest frame and then we will find the solution for the u of p and v of p , in the rest frame and then we do a boost to find the general solution, in any frame. So, that is what we will do, in the rest frame these two equations will look like the following. This equation looks like $\gamma^0 \not{p}_0 - m$ acting on u of p equal to 0 and the second equation looks like $\gamma^0 \not{p}_0 + m$ acting on v of p equal to 0, but since p_0 equal to m . Therefore, the same plus $\gamma^0 - 1$ u , p again here is m 0 is equal to 0, here again m 0 equal to 0 m 0 equal to 0 $\gamma^0 + 1$ v of m 0 equal to 0. To solve this, we will choose one particular representation for the gamma matrices.

(Refer Slide Time: 25:23)

And then the solutions look very simple in this representation where, gamma 0 is 1 0 0 minus 1 and gamma i are 0 sigma i minus sigma i 0. You can see that this set of gamma matrices also satisfy the Clifford algebra gamma mu gamma nu equal to 2 eta mu nu. So, they can be represented for gamma matrices, the Dirac gamma matrices, in this representation these two equations have very simple solution.

We can see that, there are two linearly independent solutions for this equation and two linearly independent solutions for this equation. Gamma 0 minus 1 will have equal to 0 0 0 minus 2, 2 times identity. So, this suggests that the linearly independent solution therefore, gamma 0 minus 1 u m 0 equal to 0 m plus. There are two linearly independent solutions for u m 0, which I will denote as u 1 m 0 which is 1 0 0 0 and u 2 m 0 and u 2 m 0 is 0 1 0 0. Similarly, you can solve the other equation here gamma 0 plus 1 v equal to 0 again there will be two linearly independent solutions for v.

(Refer Slide Time: 27:28)

$$\{\gamma^\alpha, \gamma^\beta\} = 2\eta^{\alpha\beta}$$

$$(\gamma^0 - 1) = \begin{pmatrix} 0 & 0 \\ 0 & -2\mathbb{1} \end{pmatrix}$$

$$(\gamma^0 - 1)U(m,0) = 0 \Rightarrow U_1(m,0) = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

$$U_2(m,0) = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}$$

$$U_3(m,0) = \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \end{pmatrix}$$

$$U_4(m,0) = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}$$

This is given by $v_1 = (1, 0, 0, 0)$ and $v_2 = (0, 0, 0, 1)$. You can find the most general solution, but even without finding the solution in the general frame, by performing a Lorentz boost, we can deduce a number of properties for this Dirac spinors of u of p and v of p . Now since there are two linearly independent solutions for u and two linearly independent solutions for v .

(Refer Slide Time: 28:22)

$$U_\gamma(p), v_\gamma(p)$$

$$\gamma = 1, 2$$

I will denote them as u_r of p and v_r of p where, r runs from 1 and 2. Therefore, I should clarify this symbol once more, this is a four component spinor for r equal to 1, as well as 2. And similarly, v_r of p again for equal to 1 and 2, these are four component spinor.

(Refer Slide Time: 28:50)

So, we have four, four component spinors which are u_1 of p , u_2 of p , v_1 of p and v_2 of p , they are the components. So, these are just columns you have four entries for u_1 , four entries for u_2 and so on. So, I will denote their components by alpha beta and so on. So, I have u_α of p where alpha runs from 1 to 2 and so on. So, these indices I will denote as 1, 2 and then the components of u_1 , u_2 , u_3 , u_4 etcetera those I will denote by using this symbol alpha. So, you have $u_{r\alpha}$ of p for the components of these spinors and similarly, you have $v_{s\beta}$ of p . We would like to know, what is this notation here, \bar{u}_r of p , u_s of p .

Student: ((Refer time: 30:13))

They are as usual, just like here, you can just contract them by the usual metric $\eta_{\mu\nu}$ and so on. So, u_α is simply $\eta_{\alpha\beta} u_\beta$ and so on, but these are not raised lower, they are raised and lowered r and s indices are raised and lowered by the unit matrix. So, let us look at this quantity here.

This is Lorentz invariant quantity because, we have already seen earlier that $\bar{\psi}\psi$ is invariant under Lorentz transformation. When you perform a Lorentz transformation, u

in fact because this they just differ by a number, u transforms the same way ψ transforms. So, you get a u bar goes to u bar u r bar of p under Lorentz transformation goes to u r bar p S inverse λ . So, this quantity is Lorentz invariant so you can compute this in any invariant especially, we can go to the rest frame and evaluate this quantity here. So, this is same as u bar r of m 0, u s of m 0 and you know what are these u 1, u 2 you already know, from this expression here.

(Refer Slide Time: 32:11)

$$u_{r\alpha}(p), v_{s\beta}(p) \quad u^\alpha = \gamma^\alpha \beta u_p$$

$$\bar{u}_r(p) u_s(p)$$

$$= \bar{u}_r(m, 0) u_s(m, 0) = \delta_{rs}$$

$$\bar{v}_r(p) v_s(p) = -\delta_{rs}$$

$$\bar{u}_r(p) v_s(p) = 0 = \bar{v}_r(p) u_s(p)$$

So, you see by putting explicitly the values for u bar and u s that, this is nothing but δ_{rs} . Similarly, you can show that v bar r of p , v s of p is equal to minus δ_{rs} . Whereas, u bar r of p , v s of p is equal to 0, which is also equal to v bar r of p u s of p . So, by explicit computations and using Lorentz invariants so, we have seen that the momentum space, the spinors in the momentum space obey these following relations.

(Refer Slide Time: 33:30)

$\bar{u}_r(p) u_s(p) = \delta_{rs}$, $\bar{v}_r(p) v_s(p) = -\delta_{rs}$, $\bar{u}_r(p) v_s(p) = 0 = \bar{v}_r(p) u_s(p)$. We will extensively use all these relations later on. Unlike $\bar{u}_r(p) u_s(p)$, this quantity $\bar{u}_r(p) \gamma^0 u_s(p)$ is no longer Lorentz invariant. So, however we can just use the Dirac equation and then we can evaluate, let us say, this quantity by using the Dirac equation.

So, let us see what are the, what is the expression for this quantity, this is nothing but $\bar{u}_r(p) \gamma^0 u_s(p)$. By definition of \bar{u} this is simply given by this. Now, we use the Dirac equation for u_s , u_s of p obviously this Dirac equation $\not{p} u_s(p) = m u_s(p)$. If you take the Hermitian conjugate this equation, then you will get the Dirac equation obeyed by \bar{u}_s of p and the Dirac equation for \bar{u} is given by $\bar{u}_s(p) (\not{p} - m) = 0$.

(Refer Slide Time: 35:57)

$$\begin{aligned} \bar{u}_r(p) u_s(p) &= \delta_{rs} \\ \bar{u}_r(p) u_s(p) &= -\delta_{rs} \\ \bar{u}_r(p) u_s(p) &= 0 = \bar{u}_r(p) u_s(p) \\ u_r^\dagger(p) u_s(p) &= \bar{u}_r(p) \gamma^0 u_s(p) \\ (\not{p} - m) u_s(p) &= 0 \Rightarrow u_s(p) = \frac{1}{m} \not{p} u_s(p) \\ \Rightarrow \bar{u}_r(p) (\not{p} - m) &= 0 \end{aligned}$$

So, to evaluate this quantity $u_r^\dagger(p) u_s(p)$ what I can do is, that I can use these two equations and especially, for $u_s(p)$ I will substitute $1/m \not{p} u_s(p)$. And for $\bar{u}_r(p)$, similarly we can do, we can write it as $\bar{u}_r(p)$.

(Refer Slide Time: 36:31)

$$\begin{aligned} u_r^\dagger(p) u_s(p) &= \frac{1}{2} (\bar{u}_r(p) \gamma^0 u_s(p) + \bar{u}_r(p) \gamma^0 u_s(p)) \\ &= \frac{1}{2m} (\bar{u}_r(p) \not{p} u_s(p) + \bar{u}_r(p) \not{p} u_s(p)) \\ &= \frac{1}{2m} (\bar{u}_r(p) \not{p} u_s(p)) \\ &= \frac{p_0}{m} \bar{u}_r(p) u_s(p) \\ &= \frac{p_0}{m} \delta_{rs} \end{aligned}$$

So, this is $\bar{u}_r(p) \gamma^0 u_s(p)$, which is half of the same quantity this plus $\bar{u}_r(p) \gamma^0 u_s(p)$. And in the first equation, I will write for $u_s(p)$ $1/m \not{p} u_s(p)$ and in the second equation for $\bar{u}_r(p)$, I will write $1/m \bar{u}_r(p) \not{p}$. So, this is nothing but $1/2m \bar{u}_r(p) \not{p} u_s(p) + \bar{u}_r(p) \not{p} u_s(p)$

p. It is straight forward and this implies you have $\frac{1}{2m} \bar{u}_r(p)$ anti-commutator of γ_0 slash $u_s(p)$. And what is anti-commutator of γ_0 slash? γ_0 slash anti-commutator is $p_\mu \gamma_0 \gamma_\mu$ anti-commutator. So, this is equal to $2 p_\mu \eta_{\mu\nu}$ which is $2 p_0$. So, what we have got here is, this is $\frac{p_0}{m}$ which is just a number. So, I can just pull it out $\bar{u}_r(p) u_s(p)$ so, this is nothing but $\bar{u}_r(p) u_s(p)$ is simply δ_{rs} . So, you get $\frac{p_0}{m} \delta_{rs}$.

(Refer Slide Time: 38:57)

$$\bar{u}_r(p) u_s(p) = \delta_{rs}$$

$$\bar{v}_r(p) v_s(p) = -\delta_{rs}$$

$$\bar{v}_r(p) u_s(p) = 0 = \bar{u}_r(p) v_s(p)$$

$$u_r^\dagger(p) u_s(p) = \frac{p_0}{m} \delta_{rs}$$

So, to this I can add this relation $\bar{u}_r(p) u_s(p) = \frac{p_0}{m} \delta_{rs}$. So, what we did is that, we have, we found the solution in the rest frame and then from using these, the four linearly independent solutions in the rest frame, we have derived some important identity.

(Refer Slide Time: 39:44)

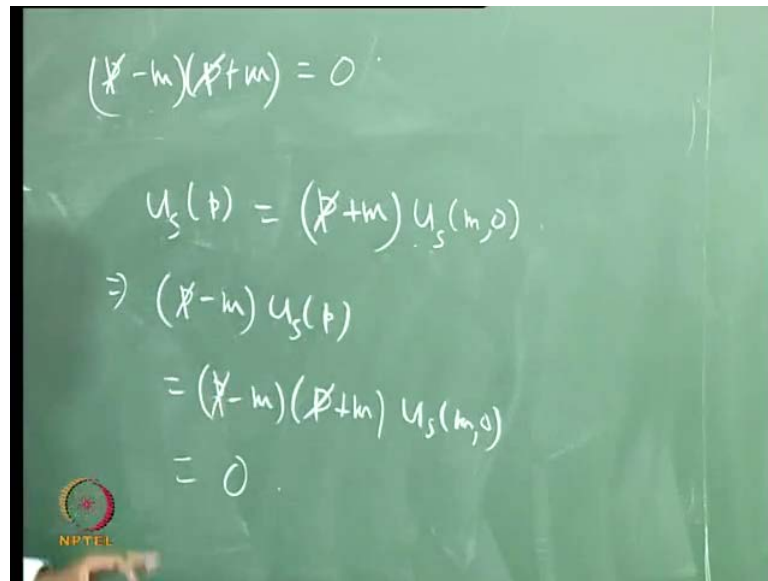

$$\begin{aligned}(\not{p} - m)(\not{p} + m) &= 0 \\ \text{L.H.S.} &= (\not{p})^2 - m^2 \\ &= p_\mu \gamma^\mu p_\nu \gamma^\nu - m^2 \\ &= p_\mu p_\nu \gamma^\mu \gamma^\nu - m^2 \\ &= \frac{1}{2} p_\mu p_\nu \{ \gamma^\mu, \gamma^\nu \} - m^2 \\ &= p^2 - m^2 = 0\end{aligned}$$

The chalkboard also features the NPTEL logo in the bottom left corner.

What we will do now is that, we will find the general solution for u s p in any general frame, this you can do by using two ways. First is of course, can use a boost and then you can construct the solution, the general solution for any arbitrary momentum. We will not do that instead what we will do is, we will use some identities like $\not{p} - m$ times $\not{p} + m$ equal to 0. Using this identity we will construct the most general solution for any arbitrary p , before that let me prove to you that this is in fact this is 0. This is nothing but p slash square minus m square, but p slash square is $p_\mu \gamma^\mu p_\nu \gamma^\nu$ minus m square.

So, this is $p_\mu p_\nu \gamma^\mu \gamma^\nu$ minus m square, but because of the symmetry here you can write it as half $p_\mu p_\nu$ anti-commutator of $\gamma^\mu \gamma^\nu$, for the first term. So, this is minus m square, but this is nothing but twice $\eta_{\mu\nu}$ so, this is p square minus m square and p square is m square therefore, p square minus m square is equal to 0 and hence, $\not{p} - m$ times $\not{p} + m$ equal to 0.

(Refer Slide Time: 41:42)

$$\begin{aligned}(\not{p} - m)(\not{p} + m) &= 0 \\ u_s(p) &= (\not{p} + m) u_s(m, 0) \\ \Rightarrow (\not{p} - m) u_s(p) &= (\not{p} - m)(\not{p} + m) u_s(m, 0) \\ &= 0\end{aligned}$$

Therefore, if you consider this $u_s(m, 0)$, this quantity is a solution to the Dirac equation. Using this identity, if I denote this to be, if I define $u_s(p)$, if I denote $u_s(p)$ to be $(\not{p} + m) u_s(m, 0)$. Then this quantity, then this is a solution to the Dirac equation and for s equal to 1 and 2, there are two linearly independent solutions here, for arbitrary momentum. Because, obviously this simply implies that $(\not{p} - m)$ acting on the $u_s(p)$ is nothing but $(\not{p} - m)(\not{p} + m) u_s(m, 0)$ and because, this is 0, this quantity is 0. So, for any u_s of this type it is actually a solution to the Dirac equation. So, therefore there are, I have two linearly independent solutions for s equal to 1 and 2, constructed from $u_s(m, 0)$.

(Refer Slide Time: 43:23)

Only thing that we need to, I need to make sure is that, this normalization condition is satisfied. And this will be normalized, if you define u_s to be p slash m divided by square root of $2m$ times m plus E , I guess $u_s(m, 0)$. Then, this u_s is normalized to delta r s, it is normalized such that $u_s(p)$ by $u_r(p)$ is equal to delta r s. So, I have the most general solution, which I constructed by using this identity. Similarly you have, you can construct solution for v_s of p , which is minus p slash plus m divided by $2m$, m plus E v_s of $m, 0$.

Student: Can you just repeat, how it is the most general solution?

It is just, it is the solution is satisfied for any value of momentum and then there are two linearly independent solutions, that is all. And you can in fact show that this solution in fact here is, they can be obtained by Lorentz boost from the solution in the rest frame.

(Refer Slide Time: 45:34)

Now what I will do is that, I will introduce a projection operator, which I will define to be this, $\Lambda_+(p) = \sum_{s=1}^2 u_s(p) \bar{u}_s(p)$. I will show that this is in fact a projection operator, but before that I will explain what do you mean by this symbol. You already know what is $\bar{u} u$, this is just a number because, this is a row and this is a column and then you can multiply it by using ordinary matrix multiplication, this is number. This product simply can be used to construct a 4 by 4 matrix out of u and \bar{u} . And I define it in terms of its components, in the sense that $\Lambda_+(p)_{\alpha\beta}$, this symbol simply means that $\sum_{s=1}^2 u_{s\alpha}(p) \bar{u}_{s\beta}(p)$, that is all, that is what I mean by this.

(Refer Slide Time: 47:21)

So, now let us consider this u s of p , I already know is given by this and you can show that this is 1 over 2 m times m plus E times, this t slash plus m sum over s u s m 0 u bars m 0 p slash plus m , this is straight forward. Now what is this quantity here? Again I can use the definition of this, that I have introduced and it turns out that u s m 0 u bar s m 0 is nothing but this. So, this in our representation, in the representation that, in which we have solved for u s m 0 this is simply equal to half times 1 plus γ_0 . So, it is very straight forward because, u s the lower two components are 0 's. So, only thing that is non-zero is this so, you have 1 0 1 0 with 1 0 plus 0 1 which is nothing but, identity matrix in the first sector and then all the other things are 0 .

(Refer Slide Time: 50:02)

So, I will use this identity here, then I have lambda plus p equal to 1 over 2 m, m plus E P slash plus m 1 plus gamma 0 over 2 p slash plus m. And you can use, you can simplify this algebra here to show that, this is nothing but p slash plus m divided by 2 m. Similarly, I can introduce lambda minus.

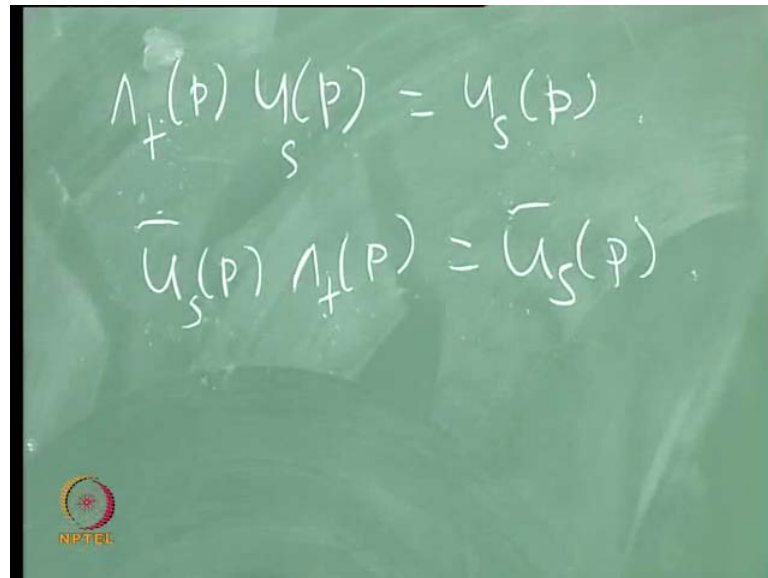

(Refer Slide Time: 51:03)

So, I leave it as an exercise for you to show that this is p slash m over 2 m and if I define lambda minus of p equal to minus sum over s equal to 1 to 2 v s of p tensor with v s bar of p. Then, this quantity will be equal to minus p slash plus m divided by 2 m. So, from

here I get a complete next relation which is lambda plus of p plus lambda minus of p is identity or if I want to write it in terms of components. Then it simply means that sum over s is equal to 1 to 2 u s alpha p u bar s beta p minus v s alpha p v bar s beta p is equal to delta alpha beta.

(Refer Slide Time: 52:10)

$$\Lambda_+(p) u_s(p) = u_s(p)$$

$$\bar{u}_s(p) \Lambda_+(p) = \bar{u}_s(p)$$

I will also leave it as a home work for you to show that, lambda plus acting on lambda plus p acting on the u p u s p equal to u s p, that is why it is called as a projection operator. Similarly, u bar s p lambda plus p is u bar s p and similar relations for lambda minus acting on v. So, what we did is, we constructed the plain wave solution for Dirac equation. So, the most general solution is of course, is a superposition of these plain wave solutions. What we will do is, in the next lecture we will take the most general solution and quantize the Dirac field and then we will see what are the implications of this, alright?
