(Refer Slide Time: 00:10)

So, in the last lecture we have constructed a Lagrangian density for the Dirac spinor, in the Lagrangian density is given by  $\bar{\psi} i \gamma^\mu \partial_\mu \psi - m \bar{\psi} \psi$ , from which we can derive the equation of motion. And the equation of motion for  $\psi$  is given by,  $i \gamma^\mu \partial_\mu \psi - m \psi = 0$ , this admitted both positive frequency as well as negative frequency modes. They are given by  $\psi = u(\mathbf{p}) e^{-i p \cdot x}$  and  $\psi = v(\mathbf{p}) e^{i p \cdot x}$ . So, if you try to look for a solution of this kind, then we see that there are two linearly independent solution.

So, there are two linearly independent four component spinors recycle as  $u_s(\mathbf{p})$  and if I look for a solution which is of the kind  $\psi = v(\mathbf{p}) e^{i p \cdot x}$ . Then again, there are two linearly independent four component spinors, which I will denote as  $v_s(\mathbf{p})$ . These, where  $s$  runs from 1 to 2 so these spinors  $u_s(\mathbf{p})$  and  $v_s(\mathbf{p})$  they satisfy a number of identities, which we have derived in the last lecture, which I will summarize here,  $\bar{u}_r(\mathbf{p}) u_s(\mathbf{p}) = \delta_{rs}$ . Then  $\bar{v}_r(\mathbf{p}) v_s(\mathbf{p}) = -\delta_{rs}$  and

then sum over  $s$ ,  $u$  s p u bar s p equal to p slash plus m over 2 m, then an analogue statement for  $v$ , which is sum over  $s$  v s of p v s star of p equal to p slash minus m over 2 m and a number of identities, in addition to all these things.

What you will do is that, we will use these solutions, these linearly independent solutions to construct the most general solution and then we will see what happens, when we quantum Dirac field. So, the most general solution will of course be a, linear superposition of solution of these kinds.

(Refer Slide Time: 04:04)

Therefore,  $\psi$  of  $x$  can be written as the sum over  $s$  integration  $d^3 p$  over  $(2\pi)^3$  and you will use a slightly different normalization  $m$  over  $\omega_p$ . You can see that, this is again Lorentz invariant because  $m$  is the rest mass of particles, which is a Lorentz invariant quantity. And this integration measure is you have already seen is Lorentz invariant, then the coefficient  $i$  will call them  $c$  s of  $p$ ,  $u$  s p e to the power minus  $i p \cdot x$  and then  $d$  s dagger of  $p$ ,  $v$  s e to the power plus  $i p \cdot x$ , this is for  $\psi$ .

Now, let us try to look at what is the conjugate momentum to the field  $\psi$ . This is given by  $\pi_\psi$  equal to be momentum conjugate to  $\psi$ , then this is  $\frac{\delta \mathcal{L}}{\delta (\partial_0 \psi)}$ . And from the expression for the Dirac Lagrangian you can see that, this quantity is the given by,  $\bar{\psi} \gamma_0$ , which is equal to  $i$  and  $\psi$  dagger of  $x$ . So, you might think that the equal time commutation relations again will be something of this kind,  $\pi_\psi$  of  $t$  and  $x$ ,  $\pi_\psi$  of  $t$   $x$  prime equal to  $i \delta(x - x')$ . However we have already

seen, if we have commutation relations of these kinds, then we get some computation relations for this operator  $c_s$  and  $d_s^\dagger$  and then this gives as a spectrum for particles with a Bose Einstein statistics.

We do not want particles of half integer spin to obey Bose Einstein statistics, we want them to obey the Fermi Dirac statistics. And that cannot be achieved by considering a commutation relation, but in the field and the conjugate momentum, what we will do is, we will instead of commutation relations, we will have anti commutation relations instead.

And then we will see what happens, when we consider the anti-commutation relation anti commutator of the field and the corresponding conjugate momentum is  $i$  times  $\delta(x - x')$ . This is what we will assume and then we will correspondingly get some anti-communication relations, but in these operator  $c_s(p)$  and  $d_s^\dagger(p)$ , we will see that these anti commutation relations give a spectrum of particles which obey the Fermi Dirac statistics.

So, this, a must saying that  $\psi(x, t) \psi^\dagger(x', t)$  the equal time anti commutation relations is given by  $\delta(x - x')$ . We can use the anti-commutation relation and derive the corresponding anti commutation relations per  $c_s(p)$  and  $d_s(p)$ . Instead what I will do is, I will give the anti-commutation relations for  $c_s$  and  $d_s$ . And then we will check that this anti commutation relation is satisfied, provided this operator  $c_s$  and  $d_s^\dagger$  satisfy the following anti-commutation relations.

(Refer Slide Time: 09:13)

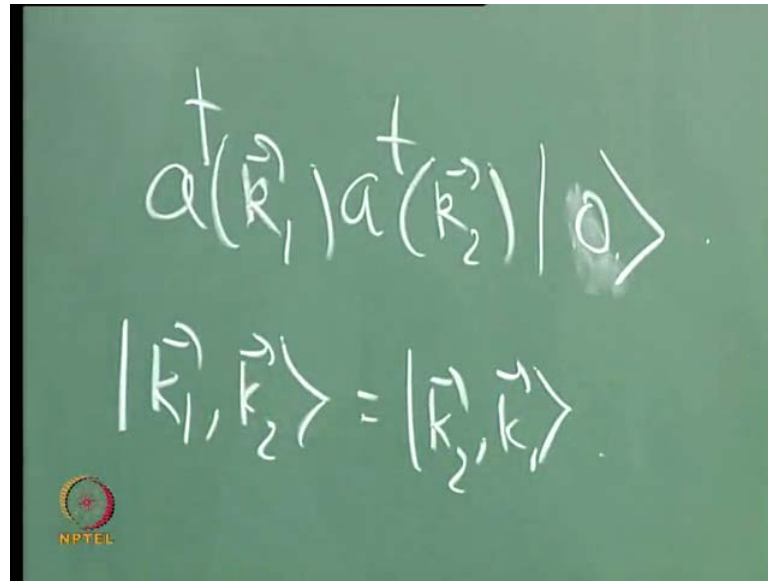

So, the anti-commutation relations satisfied by the  $c$ 's and  $d$ 's is given by  $c_r(\vec{p}) c_s^\dagger(\vec{p}') = c_s^\dagger(\vec{p}') c_r(\vec{p}) + (2\pi)^3 \frac{\omega(\vec{p})}{m} \delta(\vec{p}-\vec{p}') \delta_{rs}$ . And similar relation for the  $d$ 's  $d_r(\vec{p}) d_s^\dagger(\vec{p}') = d_s^\dagger(\vec{p}') d_r(\vec{p}) + (2\pi)^3 \frac{\omega(\vec{p})}{m} \delta(\vec{p}-\vec{p}') \delta_{rs}$ . Whereas the anti-commutations relation between  $c_r(\vec{p}) c_s(\vec{p}') = 0$ ,  $c_r(\vec{p}) d_s(\vec{p}') = 0$  and  $c_r(\vec{p}) d_s^\dagger(\vec{p}') = 0$ . And then the conjugate of these two equations, they have might conjugate of these equations.

So, these are all the anti-communication relations satisfied by this operator  $c$ 's and  $d$ 's. What we will do in the following is, we will assume this anti commutation relations and then from there we will derive the anti-commutation relations for  $\psi$  and  $\psi^\dagger$ . So, let us do that.

Student: What will happen to the anti-commutation relation on this pi end side?

Then you will get here, you can I mean just like a, the case of a complex scalar field, you will have commutation relations here instead of anti-commutation relations. Then you try to contract multi particles states from the vacuum.

(Refer Slide Time: 12:05)

$$a^\dagger(\vec{k}_1) a^\dagger(\vec{k}_2) |0\rangle$$
$$|\vec{k}_1, \vec{k}_2\rangle = |\vec{k}_2, \vec{k}_1\rangle$$

So, how to multi particle states are constructed a dagger of  $k_1$ , a dagger of  $k_2$ , let us consider a two particle state, constructed art of vacuum. Because, a dagger and a commute therefore this  $k_1, k_2$  is same as  $k_2, k_1$ . This state does not change under the exchange of the quantum number of shear. So, that why this particle like states actually obey the Bose Einstein statistics. What we will like to is, we will like to if this particle like states obey Fermi Dirac statistics and hence you would think that, this operators should actually obey some anti-commutation relations.

That is the reason we start with the anti-commutation relations for the field and the corresponding conjugate momentum. So, let us, let us derive this equation from these relations, I will consider the components of the spinor shear it will be easy for us to do the competition intense of the components. So, the components here the both  $\psi$  and  $\psi^\dagger$  are four component spinors.

(Refer Slide Time: 13:53)

And what I would like to consider is psi of psi alpha x t commutating with psi dagger beta x prime t, the equal time anti commutation relations. I already know what is the expression for psi.

(Refer Slide Time: 14:25)

This trivial tells me what is the expression for psi dagger, what is psi dagger it is sum over x, integration d q p prime i will use for the integration variable. And for this one, I will use r 2 pi cube m over omega p prime c r dagger of p prime u s dagger of p prime, u r dagger of p prime, e to the power of minus i plus i p prime and x prime here. I am

considering  $x$  prime and this one plus  $d r$  dagger of  $p$  prime,  $d r$  of  $p$  prime,  $v r$  dagger of  $p$  prime  $e$  to the power minus  $i p$  prime dot  $x$  prime. So, when I take the anti-commutation of this with this, I will consider  $\psi$  alpha of  $x$ . So, there will be a  $u$  s alpha here, there will be a  $v$  s alpha here and similarly, I will consider  $\psi$  dagger beta. So, there will be a beta, beta th component of  $u r p$  prime and beta th component of  $v$  dagger  $r$  of  $p$  prime.

Now, what will I get for this anti commutator here, it will. So, the first step and this it will give some anti commutator here, which is none 0, then anti commutator of this term and this term trivially vanishes, because of this relation here. Similarly, anti commutator of this with this will vanish, because of the conjugate of this equation, conjugate of this equation. And then the anti commutator of this, with this which is not going to vanish so these are the terms which are going to survive, the anti commutator step this with this, the anti commutator term this, with this term.

(Refer Slide Time: 17:10)

So, let us look at these two terms, in fact, i can call this to be  $\psi$  plus and this to be  $\psi$  minus, then  $\psi$  plus  $\psi$  dagger minus and  $\psi$ . So, these, the commutation relations with the non-vanishing, these are the anti-commutation relations, which are not vanishing. So, this is sum over  $r$ , sum over  $s$  and then you have integration  $d$  cube  $p$  divided by  $2 \pi$  pi cube  $m$  over  $\omega$   $p$ . And again, you will have integration number  $p$  prime, which is  $p$  d cube  $p$  prime over  $2 \pi$  pi cube  $m$  over  $\omega$   $p$  prime and then there will be two terms.

And I will erase this and then so this times the anti-commutator of  $c_s$  of  $p$ ,  $c_r$  dagger of  $p$  prime and then  $u_s$  alpha  $p$ ,  $u_r$  dagger beta  $p$  prime and then  $e$  to the power  $i p \cdot x - p' \cdot x$  this is the first step. And similarly, I will have one more term, which is given by  $d_s$  dagger of  $p$ ,  $d_r$  of  $p$  prime,  $v_s$  alpha of  $p$ ,  $v_r$  dagger beta of  $p$  prime and then  $e$  to the power  $plus i p \cdot x - p' \cdot x$ .

So, this is what we will get these are the two non-vanishing terms. Now let simplify this you know, what is anti-commutation relation here, it just up to some normalization its  $\delta_{rs}$  times,  $\delta_{p-p'}$ . So, let us substitute that we will substitute that and then you will carry out the  $p$  prime integration.

So, if we substitute that because of the chronicle delta,  $\delta_{rs}$  the sum over  $r$  we can just carry out and then it will be a sum over  $u_s$  alpha  $p$ ,  $u_s$  beta dagger  $p$  prime, but there is a chronicle, there is a Dirac delta,  $\delta_{p-p'}$ , which will make both the  $p$  and  $p$  prime equal, if you carry out the  $p$  prime integration.

(Refer Slide Time: 21:15)

Now look at this term here, this term is  $e$  to the power  $i$ , the  $e$  to the power  $minus i$ ,  $p \cdot x$  is  $\omega t - \vec{p} \cdot \vec{x}$ , this three vector product  $p \cdot x$ . And then here,  $p' \cdot x'$  is  $minus \omega'$  of  $\omega p'$  is what this 0th component of  $p'$  dot, 0th component of  $x'$  means  $t$  because here we are considering equal time and the commutation relations.

So omega prime of p t and then plus p prime dot x prime, this three vector product, so because the whole thing is multiplied by, multiplied by delta, Dirac delta p minus p prime therefore, I can substitute here instead of, in the place of p prime I can just write p. Then the t dependents will cancel from here and here so what you have is, e to the power plus i p dot x minus x prime. That is what you are going to get here when you, when you carry out the p prime integration shear and state when you carry out the p prime integration, because of the opposite sign here. What you will get here is, everything will be the same except that, you will get e to the power minus i p dot x minus x prime. This is what you are going to get so let us let us carry out the commutation.

(Refer Slide Time: 23:16)

So, this sum over r will go away because of the chronicle delta. So, you will have only sum over s and then integration of d cube p over 2 pi cube, m over omega p, this m over omega p prime will cancel here. This normalization omega over m and this 2 pi cube again will cancel, this 2 pi cube and I am carrying out this d cube p prime integration. So, the Dirac delta will go away. Finally, what we will be left with is u s alpha of p u s beta dagger of p again, because of the integration over p prime and then e to the power of i p dot x minus x prime.

Whereas, in the second term I will have a plus v s alpha p, v s dagger beta of p, e to the power minus i p dot x minus x prime. This is what you will get, when we substitute for

the anti-commutation relations for c s and d s and so on. Now you look at this sign here, here it comes with the plus sign, but here it comes with the minus sign.

(Refer Slide Time: 25:24)

$$\frac{d^3p}{(2\pi)^3} \frac{1}{\omega(\vec{p})} \left[ \left\{ c_s(\vec{p}), c_r^\dagger(\vec{p}') \right\} u_{s\alpha}(\vec{p}) u_{r\beta}^\dagger(\vec{p}') e^{-i(\vec{p}\cdot\vec{x} - p'\cdot\vec{x}')} \right. \\ \left. + \left\{ d_s^\dagger(\vec{p}), d_r(\vec{p}') \right\} v_{s\alpha}(\vec{p}) v_{r\beta}^\dagger(\vec{p}') e^{i(\vec{p}\cdot\vec{x} - p'\cdot\vec{x}')} \right] \\ \left[ u_{s\alpha}(\vec{p}) u_{s\beta}^\dagger(\vec{p}) e^{i\vec{p}\cdot(\vec{x}^2 - \vec{x}'^1)} + v_{s\alpha}(\vec{p}) v_{s\beta}^\dagger(\vec{p}) e^{-i\vec{p}\cdot(\vec{x}^2 - \vec{x}'^1)} \right]$$

If I want to take this is a common factor, what I can do is in this second term. For example, I can seem this integration variable p to minus p and when I do that, here I will have a plus sign, but in the arguments v s will change this sign. Yes or no?

(Refer Slide Time: 25:50)

$$\frac{d^3p}{(2\pi)^3} \frac{1}{\omega(\vec{p})} \left[ \left\{ c_s(\vec{p}), c_r^\dagger(\vec{p}') \right\} u_{s\alpha}(\vec{p}) u_{r\beta}^\dagger(\vec{p}') e^{-i(\vec{p}\cdot\vec{x} - p'\cdot\vec{x}')} \right. \\ \left. + \left\{ d_s^\dagger(\vec{p}), d_r(\vec{p}') \right\} v_{s\alpha}(\vec{p}) v_{r\beta}^\dagger(\vec{p}') e^{i(\vec{p}\cdot\vec{x} - p'\cdot\vec{x}')} \right] \\ \left[ u_{s\alpha}(\vec{p}) u_{s\beta}^\dagger(\vec{p}) e^{i\vec{p}\cdot(\vec{x}^2 - \vec{x}'^1)} + v_{s\alpha}(\vec{p}) v_{s\beta}^\dagger(\vec{p}) e^{-i\vec{p}\cdot(\vec{x}^2 - \vec{x}'^1)} \right]$$

So, let us let us do that, therefore, what I will have here is v s of minus p and v s dagger beta minus p and here, I will have a plus.

(Refer Slide Time: 26:12)

Now, we can just take this out so sum over s, d cube p over 2 pi cube m over omega p and then e to the power i p dot x minus x prime and then u s alpha of p.

(Refer Slide Time: 26:45)

u s beta dagger of the p prime, p again plus v s alpha minus p v s dagger beta of minus p. So, it is almost look like we are having a Dirac delta function here, but it is not a, not yet because of this term mainly inside this square bracket. What is this quantity here? When you carry this sum over x what you get? So, in the beginning of this lecture I have, I have written down some of the identities that you have proof in the last lecture.

(Refer Slide Time: 27:45)

$$\sum_s U_s(\vec{r}) \overline{U_s(\vec{r})} = \frac{l+1}{2m}$$

$$\sum_s U_s(\vec{r}) U_s^\dagger(\vec{r}) = \frac{1}{2m} (l+1) r^0 = \frac{1}{2m} (p_1 r^0 + p_2 r^0 + m) r^0$$

$$\sum_s V_s(\vec{r}) U_s^\dagger(\vec{r}) = \frac{1}{2m} (l-m) r^0$$

$$\Rightarrow \sum_s V_s(-\vec{r}) U_s^\dagger(-\vec{r}) = \frac{1}{2m} (p_1 r^0 - p_2 r^0 - m) r^0$$

$$\sum_s \left[ U_s(\vec{r}) U_s^\dagger(\vec{r}) + V_s(-\vec{r}) U_s^\dagger(-\vec{r}) \right] = \frac{1}{m} p_0 = \frac{\omega(\vec{p})}{m}$$

One of them is if you carry out the sum over s,  $\sum_s U_s(\vec{r}) \overline{U_s(\vec{r})}$  then this quantity is  $\frac{l+1}{2m}$  here instead of  $\sum_s U_s U_s^\dagger$ . So, if you want to get an expression for  $\sum_s U_s U_s^\dagger$ , you get some, you just multiply  $\gamma^0$  from the right. So, this is simply  $\sum_s U_s U_s^\dagger$  of  $p$  is  $\frac{1}{2m} (l+1) \gamma^0$ . Similarly,  $\sum_s V_s U_s^\dagger$  of  $p$  is  $\frac{1}{2m} (l-m) \gamma^0$ . What do you want instead is, instead is  $\sum_s V_s(-\vec{r}) U_s^\dagger(-\vec{r})$  of  $p$  is  $\frac{1}{2m} (p_1 \gamma^0 - p_2 \gamma^0 - m) \gamma^0$ . So, the second line implies  $\sum_s V_s(-\vec{r}) U_s^\dagger(-\vec{r})$  of  $p$  is equal to  $\frac{1}{2m} (p_1 \gamma^0 - p_2 \gamma^0 - m) \gamma^0$ , because of the minus here.

So, you cannot simply have a minus sign here because this 0th component does not change the sign. And minus  $m$ , whole thing multiplied by  $\gamma^0$ , whereas this one here, you can see is given by  $\frac{1}{2m} (p_1 \gamma^0 + p_2 \gamma^0 + m) \gamma^0$ , whole thing multiplied by  $\gamma^0$  from the right. So, if you add this term from this term then what you get is, the last two terms cancel so there and the first term adds.

So, you have  $\sum_s U_s(\vec{r}) U_s^\dagger(\vec{r}) + V_s(-\vec{r}) U_s^\dagger(-\vec{r})$  of  $p$  is given by  $\frac{1}{m} p_0$  and there is this  $\gamma^0$  square which is identity. So, it is just simply remember  $p_0$  is nothing but  $\omega(\vec{p})$  divided by  $m$ . If you want put the  $\alpha, \beta$  etcetera then this is just  $\delta_{\alpha\beta}$ .

(Refer Slide Time: 31:20)

$$\sum_s u_s(\vec{r}) u_s^\dagger(\vec{r}) = \frac{l+1}{2h}$$

$$\sum_s u_s(\vec{r}) u_s^\dagger(\vec{r}) = \frac{1}{2m} (l+1) r^0 = \frac{1}{2m} (l r^0 + l r^1 + 1) r^0$$

$$\sum_s v_s(\vec{r}) v_s^\dagger(\vec{r}) = \frac{1}{2h} (l-1) r^0$$

$$v_s(-\vec{r}) v_s^\dagger(-\vec{r}) = \frac{1}{2h} (l r^0 - l r^1 - 1) r^0$$

$$\left[ u_s(\vec{r}) u_s^\dagger(\vec{r}) + v_s(-\vec{r}) v_s^\dagger(-\vec{r}) \right] = \frac{1}{m} l \frac{\omega(r^0)}{h} \delta_{\alpha\beta}$$

So,  $u_s \alpha$ ,  $u_s \dagger \beta$  and  $v_s \alpha$  minus  $v_s \dagger \beta$  of minus  $p$  is simply given by this times  $\delta_{\alpha\beta}$  so there will be  $\delta_{\alpha\beta}$  here. So, what we have seen here is, after doing all these calculation, this thing here inside the square bracket is nothing but  $\omega$  over  $m$   $\delta_{\alpha\beta}$ .

(Refer Slide Time: 31:55)

$$\{ \psi_\alpha(\vec{r}, t), \psi_\beta^\dagger(\vec{r}', t) \}$$

$$= \int \frac{d^3 p}{(2\pi)^3} \cdot \frac{\omega}{h} \cdot c^{u^\dagger(\vec{r} - \vec{r}')} \cdot \frac{\omega}{h} \delta_{\alpha\beta}$$

$$\{ \psi_\alpha(\vec{r}, t), \psi_\beta^\dagger(\vec{r}', t) \} = \delta(\vec{r} - \vec{r}') \delta_{\alpha\beta}$$

$$\{ c_s(\vec{r}), c_s^\dagger(\vec{r}') \} = (2\pi)^3 \frac{\omega}{h} \delta(\vec{r} - \vec{r}') \delta_{\alpha\beta}$$

So, let us substitute the here, sum over  $s$  is gone so  $d^3 p$  over  $2\pi^3$ ,  $m$  over  $\omega$  and then  $e^{i p \cdot x - x'}$ . And the whole thing is given by,  $\omega$  over  $m$   $\delta_{\alpha\beta}$  so  $m$  over  $\omega$  cancel  $\omega$  over  $m$ . And hence, I can

carry out the integration over  $p$ , when I do that, what we get is  $\psi_\alpha(x, t)$ , the equal time and anti-commutation relations,  $\psi_\beta^\dagger(x)$  probability is nothing but  $\delta(x - x')$ .

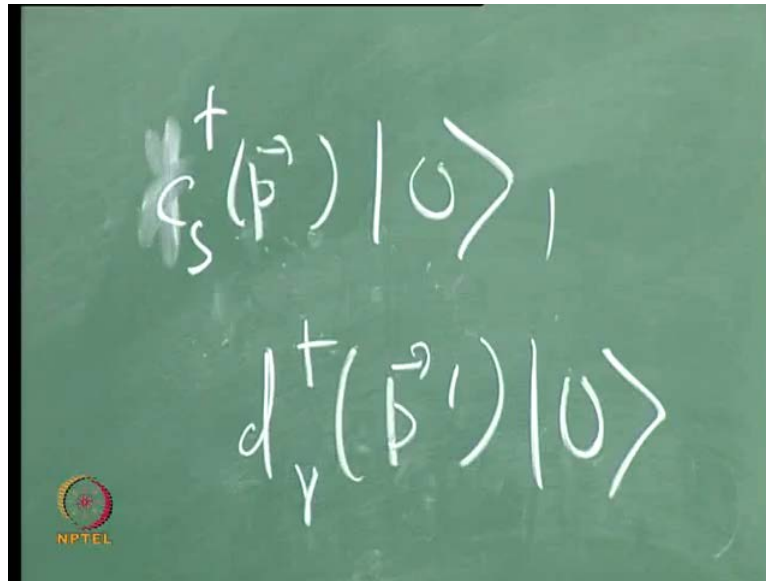

So, in order to have the four components spinor, the Dirac spinor and its conjugate momentum. To obey the equal time anti commutation relation, what we saw is that we need the coefficients  $c_r$  of  $c_r^\dagger$  to obey some equation like  $2\pi^3 \delta^3(p - p')$  and so forth. So, now as you expected already that, the  $c_r$  is like any lesson operators. So whereas, the  $c_r^\dagger$  is like creation operators again.

(Refer Slide Time: 34:37)

$$\left. \begin{aligned} c_r(\vec{p})|0\rangle &= 0 \\ d_s(\vec{p})|0\rangle &= 0 \end{aligned} \right\} \forall \vec{p}, r, s = 1, 2$$

We will have a vacuum, will define  $|0\rangle$  to be the vacuum state which is any letter by  $c_r$  for all  $p$  and for all equal to 1 and 2 and also its any letter by  $d_s$  of  $p$  equal to 0 for all  $p$  and for  $r$  and  $s$  to the 1 and 2.

(Refer Slide Time: 35:13)

$$c_s^\dagger(\vec{p})|0\rangle,$$
$$d_\gamma^\dagger(\vec{p}')|0\rangle$$

Then, the multi particle states are constructed by  $c_s^\dagger$  of  $p$  on the vacuum and so on,  $d_\gamma^\dagger$  of  $p'$  and vacuum and then a bunch of  $c$ 's and  $d$ 's. So, this way you can construct the entire Hilbert state and then you can see that, because of anti-commutation relation like this, this particle states it can be obey the Fermi Dirac statistics, instead of the Bose Einstein statistics. You can construct the energy momentum operator and these are and shown because the Dirac Lagrangian as we have seen has a  $u$  r in variance, it is a global  $u$  r invariance.

So, there will be ((Refer Time: 36:26))  $r$ 's, you can construct this  $r$ 's operator, you can see that these are, I mean these  $r$ 's, for these particle are actually opposite to these  $r$ 's, this particles of the second kind. So, if we identify these with the positive these  $r$ 's particles then these will be the negative charge particle or vice versa. So, for example if these are the electron states, these states represent the electron then these states will represent depositors. So, the important thing is that you must note is the following, for example when you consider the normal ordering, in the case of bosonic fields.

(Refer Slide Time: 37:37)

$$\begin{aligned}
 & : a(\vec{k}) a^\dagger(\vec{k}') a(\vec{k}_3) a(\vec{k}_4) a^\dagger(\vec{k}_6) : \\
 & = a^\dagger(\vec{k}') a^\dagger(\vec{k}_6) a(\vec{k}) a(\vec{k}_3) a(\vec{k}_4)
 \end{aligned}$$

We were seeing that if you have a bunch of operators and then we just consider the normal ordering of these operators, then what we have is this, a of k, a dagger of k prime, a of k 3, a of k 4, a dagger of k 6 something like this. Then what do you have? What do you get? You just for Bosonic fields this is just given by a dagger of k prime, a dagger of k 6 and then a of k, a of k 3, a of k 4 this is all you have. Now in the case of Fermionic operators, you have to be a little bit careful about moving this to the left, if it crosses one of these operators, then it changes the sign.

(Refer Slide Time: 38:55)

$$\begin{aligned}
 & : a(\vec{k}) a^\dagger(\vec{k}') a(\vec{k}_3) a(\vec{k}_4) a^\dagger(\vec{k}_6) : \\
 & : c(\vec{k}) c^\dagger(\vec{k}') c(\vec{k}_3) c(\vec{k}_4) c^\dagger(\vec{k}_6) : \\
 & = (-1)^4 c^\dagger(\vec{k}') c^\dagger(\vec{k}_6) c(\vec{k}) c(\vec{k}_3) c(\vec{k}_4) \\
 & = (-1)^4 c^\dagger(\vec{k}') c^\dagger(\vec{k}_6) c(\vec{k}) c(\vec{k}_3) c(\vec{k}_4)
 \end{aligned}$$

So, an identical, a similar relation for, for the Fermionic operator will have this,  $c$  I surprising the spin indices  $c$  of  $k$ ,  $c$  dagger of  $k$  prime,  $c$  of  $k$  3,  $c$  of  $k$  4,  $c$  dagger of  $k$  6. Let us say you have normal ordering of these operators, that you see here this operator will have to from once therefore, it will change the sign, this is just normal order product of minus  $c$  dagger of  $k$  prime  $c$  of  $k$ . And then  $c$  of  $k$  3,  $c$  of  $k$  4,  $c$  dagger of  $k$  6, but again this if you want to bring it, to the extreme left, inside the normal order product it will change the sign three times, this is minus 1 to the 4 and this is  $c$  s dagger,  $c$  dagger of  $k$  6.

So, this is simply minus  $k$  4  $c$  dagger  $k$  prime  $c$  dagger of  $k$  6  $c$  of  $k$   $c$  of  $k$  3  $c$  of  $k$  4 without any normal ordering. If there is one more operator here, then for the bosonic fields it will not make any  $c$ 's, but for the Fermi harmonic field, it will gain a minus sign. So, you have to keep track of this minus signs also, these operators, if you cross these operators once they have a minus sign, so that you need to be careful about, when you do the normal ordering.

(Refer Slide Time: 41:34)

You go and work out the expression for the energy momentum denser, what i claim is the total energy momentum has the expression it is given by,  $d$  cube  $k$  over  $2 \pi$  cube  $m$  over  $k_0$   $k$  mu sum over  $s$   $d$  s dagger of,  $c$  s dagger of  $k$   $c$  s of  $k$  minus  $d$  s of  $k$ ,  $d$  s dagger of  $k$ .

Now you want to consider it, insert the normal ordering so you have normal ordering and then the normal ordering makes this to move to the left, but it crosses one's therefore, it will change the sign. And hence, after you take the normal ordering you will get  $d^3 k$  over  $2\pi^3 m^0 k^0 k^\mu$  sum over  $s$   $c_s^\dagger(k) c_s(k)$  plus  $c_s^\dagger(k) d_s(k)$ .

So, you can take the energy operator for example and then you add term, particle states like this  $c_s^\dagger(p)$ , one particle states or  $d_s^\dagger(p)$ , at a vacuum are so on. And then you will see that, this will have one quantum of energy and so will this state have, there is nothing negative about this thing. It is not a, not a negative energy state.

(Refer Slide Time: 44:12)

You can just, at you can, this is the  $p^\mu$ , you consider a state like this or you can consider a state like this  $p^0$  on  $c_s^\dagger(p)$  or  $p^0$  acting on  $d_s^\dagger(p)$  on vacuum. You can see that both type of these particles have positive energies. So, the energy they are Eigen states of the energy operator and the Eigen value is always positive.

So, these are not negative energy states, only thing is that if you construct the charge operator, you construct the charge operator and then you act, on this, as well as on these then the Eigen value of states of this kind, will have opposite Eigen value for the state of the second kind. So, it is only these charge which is negative of this, charge of

this, this state is minus of this charging states, but the energy Eigen states are not negative, the energy is always positive.

(Refer Slide Time: 45:34)

You can write it into terms of the number of operator. For example, you can introduce an  $n_s$  of  $p$  is equal to  $c_s^\dagger p c_s$  and  $n_{\bar{s}}$  of  $p$  to be the number operator for the anti-particles,  $d_s^\dagger p d_s$ . Then this will have simply  $n_s + n_{\bar{s}}$  so these are basically the  $c_s^\dagger c_s$   $n_s$  are basically the annihilation, creation and number operators or particle.

Whereas,  $d_s^\dagger d_s$   $n_{\bar{s}}$  are the annihilation, creation and number operator for the anti-particles. So, what you will do in the next class is, we will consider some of the discrete symmetries and also will derive an expression for the Dirac propagator. And then subsequently, we will learn about the interaction of the fermions with the electromagnetic field.
