**Quantization of Real Scalar Field – IV**

We have seen that, the field operator  $\phi(x)$  is given by the form  $\int \frac{d^3k}{(2\pi)^3 2\omega} [a(\mathbf{k})e^{-ikx} + a^\dagger(\mathbf{k})e^{ikx}]$

(Refer Slide Time: 00:12)

And, in the last lecture, we have seen that, these  $a_k$ 's and  $a_k^\dagger$ 's are respectively the annihilation and creation operator. We have also defined the vacuum, which is annihilated by all the  $a_k$ 's; that is equal to 0 for all  $k$ . And, the creation operators acting on the vacuum give us one particle states, which I have denoted as  $|k\rangle$ . These one particle states are eigenstates of Hamiltonian as well as the momentum operator with eigenvalues  $\omega$  and  $k$  respectively. So, these are one particle states. And similarly, you can construct multi-particle states by acting number of  $a_k^\dagger$ 's on the vacuum –  $a_k^\dagger$   $n$  times. This will give you  $|k_1, \dots, k_n\rangle$ . And, we have also seen that, this particle like excitations actually obey Bose-Einstein statistics. So, this represents bosons. So, the excitations of the Klein-Gordon field are the bosons.

(Refer Slide Time: 02:40)

In today's lecture, we will discuss about the implications. One of them is causality. Causality basically says that, if you have two events, which I will say let us say one of them is  $x$ ; another is  $y$ ; if these are two events, which are separated by space-like distance from each other; then, if you consider an operator at this space-time point  $x$  and you consider another operator at this space-time point  $y$ ; then, measurement of one of the operators will not affect the measurement of the other operator. So, quantum mechanically what should you do? The commutation of these two. So, you consider any operator at  $x$  – any other operator, any other measurable quantity, any other observable at  $y$ . If  $x$  and  $y$  are space-like separated; if  $x$  and  $y$  are space-like with respect to each other, then the commutation of  $\phi$  of  $x$  – the operator – any operator at the space-time point  $x$  with respect with any other operator at space-time point  $y$  must ((Refer Slide Time: 04:15)) The simplest one is the observable  $\phi$  of  $x$ . If  $x$  and  $y$  are space-like, then especially  $\phi$  of  $x$  must commute with  $\phi$  of  $y$  if  $x$  and  $y$  are space-like with respect to each other. So, let us see.

We have already got the expression for  $\phi$  of  $x$  by solving the Klein-Gordon equation. We can put this expression for  $\phi$  of  $x$  here and then derive this commutation relation; and then, we can see that, they in fact commute. So, let us consider the solution for  $\phi$  of  $x$ , which is... Look at the time dependence here. Here the time dependence comes like  $e$  to the power minus  $i$   $\omega t$ ; whereas, here it comes with a plus sign –  $e$  to the power  $i$   $\omega t$ . So, this part here involves the positive frequency modes; whereas, the second

part in the expression for phi involves the negative frequency components. So, this involves the positive frequency components; whereas, this one negative frequency. We will denote this to be phi plus of x and this one to be phi minus of x, so that it will be convenience for us to do the computation. So, let us represent this to be phi plus x; whereas, this to be phi minus of x. phi plus x involves only the annihilation operators; whereas, phi minus x involves only the creation operators. So, phi plus x will commute with phi plus y; and also, phi minus x will commute with phi minus y; whereas, phi plus x may not commute with phi minus y and the vice versa. So, we can express... We can try to evaluate this commutator and express it in terms of phi plus x and phi minus x. When we do that, what will get is the following.

(Refer Slide Time: 07:33)

$$[\phi(x), \phi(y)] = [\phi^+(x), \phi^-(y)] + [\phi^-(x), \phi^+(y)]$$

$$[\phi^+(x), \phi^-(y)] = \int \frac{d^3k}{(2\pi)^3 2\omega} \frac{d^3k'}{(2\pi)^3 2\omega'} e^{-ik \cdot x} e^{ik' \cdot y} [a(k), a^\dagger(k')]$$

$$= \int \frac{d^3k}{(2\pi)^3 2\omega} e^{-ik \cdot (x-y)} = -i \Delta^+(x-y)$$

where  $\Delta^+(x) \equiv i \int \frac{d^3k}{(2\pi)^3 2\omega} e^{-ik \cdot x}$

So, phi of x, phi of y is a phi plus x, phi minus y plus phi minus x phi plus y. If we compute the first term here, we can obviously get the second term just by interchanging x and y and a sign. So, what we will do is that, we will first evaluate this commutator of phi plus of x and phi minus of y. What is this commutator? For phi plus x, we will use the variable k. So, you have d cube k over 2 pi cube 2 omega. And, for phi minus y, we can use the variable k prime. So, I have d cube k prime over 2 pi cube 2 omega prime is the integration measure. Then, I have e to the power minus i k dot x from phi plus of x and e to the power plus i k prime dot y from phi minus y. And then, I have the commutator of a k, a dagger k prime.

We already know what this commutator is. So, we can put the value of this commutator here. This commutator I have already evaluated and then this is  $2\pi^3 2\omega \delta^+(k) - \delta^-(k)$ . So, you can substitute this part in the commutator and then we can see that, this  $2\pi^3 2\omega$  will cancel with this  $2\pi^3 2\omega$ . We can integrate all to one of these  $k$  primes variable. When we do that, what we get is  $d^3k$  over  $2\pi^3 2\omega$  times  $e^{-ik \cdot x - y}$ . This is the standard notation. This is represented by something which is known as delta plus. This is equal to minus  $i$  delta plus of  $x - y$ ; where, the function delta plus of  $x$  is defined to be  $i d^3k$  over  $2\pi^3 2\omega$   $e^{-ik \cdot x}$ . So, we have already evaluated the first term.

(Refer Slide Time: 11:26)

$$\begin{aligned}
 [\phi^-(x), \phi^+(y)] &= -[\phi^+(y), \phi^-(x)] \\
 &= -i\Delta^+(y-x) = i\Delta^-(x-y) \\
 [\phi(x), \phi(y)] &= i\Delta^+(x-y) + i\Delta^-(x-y) = i\Delta(x-y) \\
 \Delta(x-y) &= \Delta^+(x-y) + \Delta^-(x-y) \\
 &= -i \int \frac{d^3k}{(2\pi)^3 2\omega} \left( e^{-ik \cdot (x-y)} - e^{ik \cdot (x-y)} \right) \\
 &= -2i \int \frac{d^3k}{(2\pi)^3 2\omega} \sin(k \cdot (x-y))
 \end{aligned}$$

The second term will simply be  $\phi^-(x)\phi^+(y)$  is simply minus  $\phi^+(y)\phi^-(x)$ . So, this is minus... The standard notation is such that there is an  $i$  here. So, there is a minus  $i$  in the definition of delta plus of  $x$ . So, this is minus  $i$  delta plus of  $x - y$ ; which is also denoted as  $i$  delta minus of  $x - y$ . When I substitute that in this expression, what I get is the commutator of  $\phi$  of  $x$  with  $\phi$  of  $y$  is  $i$  delta plus of  $x - y$  plus  $i$  delta minus of  $x - y$ ; which is defined by  $i$  delta of  $x - y$ ; where, delta of  $x - y$  is delta plus of  $x - y$  plus delta minus of  $x - y$ . When I substitute the expression for delta plus and delta minus, what I get here is  $i$  times  $d^3k$  over  $2\pi^3 2\omega$   $e^{-ik \cdot x - y}$  minus  $e^{ik \cdot x - y}$ .

Student: Minus i...

There is a minus i here.

Student: Because delta plus is minus i times ((Refer Slide Time: 14:08))

Thank you. So, when I substitute it here, I will get this commutator here to be the one without a factor of  $i$ . Somehow I am missing a factor of  $i$  somewhere. I think it is fine. So, because of this minus sign, you can express this delta of  $x$  minus  $y$  as also a sign... You get a minus... So, when you get this, what you get is minus  $2i$  sign  $k \cdot x$  minus  $y$ . And hence, the delta plus  $x$   $y$ ; this  $i$  will go away; and then, you can see that this involves integration of  $d^3k$  over  $2\pi^3 2\omega$  times  $2$  sine  $k \cdot x$  minus  $y$ . So, this delta of  $x$  minus  $y$  has several properties. First thing is that, it is an odd function of  $x$  minus  $y$ ; it is an odd function of its argument, because sine is an odd function. Second thing is that, it is Lorentz invariant.

And finally, we can show that, this in fact satisfies the Klein-Gordon equation when the argument is not 0. You can apply the Klein-Gordon operator on this delta of  $x$  minus  $y$ . And then, you can say that, it in fact satisfies the Kelvin-Gordon equation when this is nonzero. However, we would like to show that, this commutator in fact... When he says when  $x$  and  $y$  are space-like with respect to each other. Or, in other words, you would like to show that, this delta function actually becomes 0 when  $x$  minus  $y$  is space-like. So, let us do that. If you consider a quantity, which is Lorentz invariant; and, if this quantity is 0 in any one inertial frame, then it will remain 0 in all inertial frames because of Lorentz invariance. So, we will exploit that property; then, we will go to a frame, where we will compute this delta of  $x$  minus  $y$  to be 0 if  $x$  minus  $y$  space-like. And then, this will tell us that, it will always remain 0 as long as  $x$  minus  $y$  is space-like.

(Refer Slide Time: 17:32)

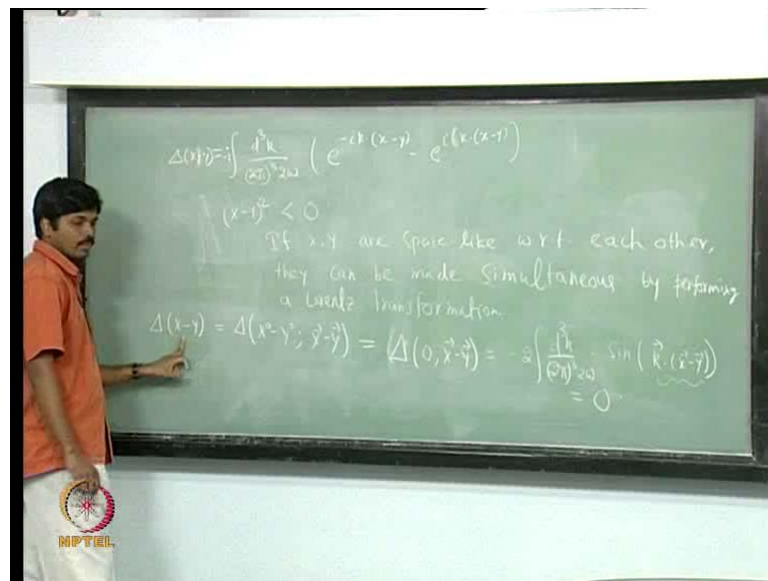

Since Lorentz invariant is so crucial, let me prove that, this delta function as in fact Lorentz invariant. This is  $d^3 k$  over  $2\pi^3 2\omega$  times minus  $i$   $e$  to the power minus  $i$   $k \cdot x$  minus  $y$  minus  $e$  to the power  $i$   $k \cdot x$  minus  $y$ . This is already Lorentz invariant; this is also Lorentz invariant. I have claimed earlier that, this integration measure here is Lorentz invariant. I have not proved it so far. So, let us prove that, this integration measure is Lorentz invariant. We know  $d^4 k$ ; unlike  $d^3 k$ ,  $d^4 k$  is Lorentz invariant. When you make a Lorentz transformation, it will give you determinant  $\lambda$ , which itself is invariant under proper ((Refer Slide Time: 18:43)) Lorentz transformation. So, this is Lorentz invariant. Delta of  $k^2$  minus  $m^2$  – you consider this quantity; where,  $k^2$  is  $k_\mu k^\mu$ , which is Lorentz invariant. Therefore, this is Lorentz invariant;  $\theta(k^0)$  is also Lorentz invariant. So, you consider this quantity here, which is Lorentz invariant.

And, let us evaluate this integration. This is integration  $d^3 k$  integration  $d k^0$ ; where,  $k^0$  runs from minus infinity to plus infinity; and, delta of  $k^2$  minus  $m^2$  is  $k^2$  minus  $k^2$  minus  $m^2$   $\theta(k^0)$ . Here  $k^0$  is a variable, which ranges from minus infinity to plus infinity. We have already seen that, this is  $\omega^2$ . So, let us rewrite this. This is  $d^3 k$  minus infinity to infinity  $d k^0$  and delta of  $k^2$  minus  $\omega^2$ . That is the argument of delta function and then  $\theta(k^0)$ . This  $\theta(k^0)$  restricts  $k^0$  to take all positive values. So, you can already see that, if you write this  $k^2$  minus  $\omega^2$ , is  $k^0$  plus  $\omega$  times  $k^0$  minus  $\omega$ ;

and, you use the proprietary delta of a x is 1 over a delta of x. So, then you will see that, you can evaluate this k 0 integration here. And, this will turn out to be d cube k over 2 omega. So, you have started with quantity, which is Lorentz invariant. And, when we have carried out the k 0 integration; and, at the end, we got this integration over d cube k over 2 omega. Therefore, this here is this factor 2 pi cube is for convenience. So, this is actually Lorentz invariant. So, we have proved that, delta of x is in fact Lorentz invariant.

(Refer Slide Time: 21:57)

Now, it is very easy to show that, this is in fact 0 when x minus y square is negative. If two events: x and y are space-like with respect to each other; then, you can perform a Lorentz transformation; and, make them simultaneous by performing a Lorentz transformation. So, I can set the 0-th component of x to be equal to the 0-th component of y. If that is the case, then... So, I start with delta of x minus y. It is delta of x 0 minus y 0; x minus y. And, I can make a Lorentz transformation – says that x 0 minus y 0 is 0. So, this is also equal to delta of... Since delta is Lorentz invariant, this will be equal to delta of 0, x minus y. What is delta of 0 x minus y? This is equal to minus 2 integration d cube k over 2 pi cube 2 omega times sign k dot x minus y. There is a minus, which will from sine; and, there are 2 i's, which will give minus. So, as a result, it will be plus.

Now, you can see that, this in fact is 0, because this is an odd function of k, which is integrated throughout the entire range of k. Therefore, you can change k to minus k; it

will give a minus sign. And hence, this will become 0. This is 0 because of the fact that, the integrand here is an odd function of  $k$ . This is not the case when the argument here is not 0. If you cannot make this to be 0, then you have a four vector here in the argument of the sine; and, it is not an odd function of  $k$  usually. So, this does not vanish when you cannot make this argument here to 0; whereas, if you can make it to 0 by a Lorentz transformation, then this vanishes identically. So, what we have seen is if  $x$  and  $y$  has space-like with respect to each other, then you can make them simultaneous. And, when they are simultaneous; these two events are simultaneous; then, the delta function vanishes. So, the delta of  $x$  becomes 0; delta of  $x$  minus  $y$  becomes 0 if you make the argument simultaneous. And, they are simultaneous if they are space-like with respect to each other.

(Refer Slide Time: 26:32)

So, the conclusion is that, this delta here vanishes if  $x$  and  $y$  are space-like with respect to each other. Since this delta of  $x$  minus  $y$  is up to a factor of  $i$  equal to the commutator of  $\phi$  of  $x$  and  $\phi$  of  $y$ ; therefore,  $\phi$  of  $x$  and  $\phi$  of  $y$  commute when  $x$  and  $y$  are space-like with respect to each other. This is what causality tells us. And hence, we have seen that, at least the Klein-Gordon theory is causal; in the sense if two events are space-like with respect to each other, then the measurement of an observable at one of these events does not affect the measurement of any other observable at the ((Refer Slide Time: 27:29)) other space-time event.

(Refer Slide Time: 27:52)

$$[\phi(x), \phi(y)] = i\Delta(x-y) = \int \frac{d^4k}{(2\pi)^4} \frac{1}{2\omega} \left( \frac{e^{-ik \cdot (x-y)}}{c} - \frac{e^{ik \cdot (x-y)}}{c} \right)$$

Green function of KG operator

$$(\partial^2 + m^2)\phi = i\delta(x-y)$$

$$\phi(x-y) = \int \frac{d^4k}{(2\pi)^4} \frac{e^{-ik \cdot (x-y)}}{c} f(k)$$

$$f(k) = \frac{1}{k^2 - m^2}$$

NPTEL

Now, we will start with this commutator... And, we can show that, this actually is a Green function of the Klein-Gordon operator. How can you do that? The Green's function for the Klein-Gordon operator can actually be obtained by solving this equation  $\partial^2 \phi + m^2 \phi = i\delta(x-y)$ . And, the solution here – if you write  $\phi(x-y)$  to be  $\int \frac{d^4k}{(2\pi)^4} \frac{e^{-ik \cdot (x-y)}}{c} f(k)$ , you can substitute it here. And, when you substitute it here, you can see that,  $f(k)$  is in fact  $1/(k^2 - m^2)$ . It is very straightforward. This delta... You can have the integral representation for this 4-dimensional delta, which is same as this without this vector  $f(k)$  here. So, you can see that, this in fact... When you operate  $\partial^2 + m^2$  over  $\phi$  here, you will get  $k^2 - m^2$  in the left-hand side. So,  $f(k)$  times  $k^2 - m^2$  is 1; and hence,  $f(k)$  is  $1/(k^2 - m^2)$ .

(Refer Slide Time: 31:07)

So, the Green function for the Klein-Gordon operator is... I will denote this as  $G$  of  $x$  minus  $y$  is  $\int \frac{d^4k}{(2\pi)^4} \frac{e^{-ik \cdot (x-y)}}{k^2 - m^2}$ . Again this  $k^2 - m^2$  has a pole when you consider the range of  $k_0$ .  $k^2 - m^2$  is nothing but  $k_0^2 - \omega^2$ . And hence, it becomes 0 when  $k_0$  is equal to plus or minus  $\omega$ . Therefore, the integrand diverges at these two points. So, you need to define what you mean by this integration. You can evaluate it in four different ways.

(Refer Slide Time: 32:23)

Therefore, if you consider the integration on the  $k = 0$  line, this represents  $k = 0$  here. This is minus  $\omega$  and this is plus  $\omega$  here. So, this integrand diverges. So, you can use, you can evaluate this integration by the means of Cauchy's residual theorem. You need to define what you mean by this integration. You can do this integration by removing these two poles in four different ways. One of them is you can in fact consider contour to be like this or you can consider the contour downwards here or you can consider one of them upwards, one of them downwards and so on. So, there are four different ways you can evaluate this integration. And, accordingly, you will get four different answers. So, depending on the boundary condition, one of these integrations will be the correct integration. Or, what you can do is you can adopt this epsilon prescription and then you can consider this integration to be the limit  $\epsilon \rightarrow 0^+$  plus integration  $\int_{-\infty}^{\infty} dk \frac{e^{-ikx}}{(k+i\epsilon)^2 - \omega^2}$  divided by  $2\pi i$   $4 \times e^{-ikx}$  divided by  $k^2 + i\epsilon^2 - \omega^2$ . You can consider  $k = 0 - i\epsilon$  also. That will tell you that you are choosing a different contour and so on. So, this is one particular way of choosing a contour. What we can do is that, we can show that we can evaluate this integration here. And then, this will be equal to the commutator of  $\phi$  of  $x$  and  $\phi$  of  $y$  under certain condition. So, let us see that.

(Refer Slide Time: 35:06)

So, let us consider this integration limit  $\epsilon \rightarrow 0^+$  plus  $\int_{-\infty}^{\infty} dk \frac{e^{-ikx}}{(k+i\epsilon)^2 - \omega^2}$  to the power  $4 \times e^{-ikx}$  to the power of  $-i k \cdot x$  divided by  $k^2 + i\epsilon^2 - \omega^2$  minus...

Student: Omega square.

Omega square; thank you. Omega square. So, this here I can write it as  $\frac{1}{2\omega}$  times  $\frac{1}{k^0 + i\epsilon - \omega}$  minus  $\frac{1}{k^0 + i\epsilon + \omega}$ . All right? And, I will substitute it here. When I substitute it here, what I get is... This  $\int_{-\infty}^{\infty} dk^0$  integration – I can write it as  $\int_{-\infty}^{\infty} dk^0$ . So, this is  $\int_{-\infty}^{\infty} dk^0 \frac{1}{2\omega}$ ; then, integration  $\int_{-\infty}^{\infty} dk^0$  over  $2\pi$ . Then, this quantity here – times  $e^{-ik^0 x}$  –  $e^{-ik^0 x}$  times  $\frac{1}{k^0 + i\epsilon - \omega}$  minus  $\frac{1}{k^0 + i\epsilon + \omega}$ .

Now, the value of this integration depends on whether  $x^0$  is positive or negative. If  $x^0$  is positive, then you can in fact show that you can... So, what is the argument here?  $e^{-ik^0 x}$ , which is  $e^{-ik^0 x^0 + i k^0 \cdot \mathbf{x}}$ . So, now, what you can do is that, you can consider the integration here on the complex  $k^0$  plane; and, you can choose this contour of this integration to be this one. This is a semi circle of radius  $R$ ; and, this is the origin; and, this runs... This here  $k^0$  – this is complex  $k^0$  plane. And, in this plane, this is the origin. This point here is  $-\omega$ ; this point here is  $+\omega$ ; and, this is  $-R$  and this is  $+R$ . You choose this contour. You consider this integration on this contour –  $\int_{-\infty}^{\infty} dk^0$  over  $2\pi$  times  $e^{-ik^0 x^0}$  times  $\frac{1}{k^0 + i\epsilon - \omega}$  minus  $\frac{1}{k^0 + i\epsilon + \omega}$ . You choose this contour integration; where, you have contour  $C$  is this one. And, you take the limit of  $R$  goes to infinity.

And, you can see that, this contour here – if  $x^0$  is positive, then this contour will in fact be equal to the integration  $-\infty$  to  $+\infty$  the same integration; where, you take instead of choosing this integration along the contour, you take it from  $-\infty$  to  $+\infty$ . That is because if  $x^0$  is positive, then the integration along this semi circle actually becomes 0; it becomes exponentially small. And, in the limit  $R$  goes to infinity, this in fact vanishes. On the other hand, if  $x^0$  is negative, then the contribution from this semicircle does not vanish. So, this is not equal to this when  $x^0$  is negative. This integration along this contour is equal to this integration, where  $k^0$  varies from  $-\infty$  to  $+\infty$  only when  $x^0$  is positive, because only then, you can see that you can take  $k^0$  to be some  $iR$ . And then, this will give you some  $e^{-R x^0}$ . And, in the limit  $R$  goes to infinity, this contribution from the semicircle in fact vanishes.

On the other hand, if  $x_0$  is negative, you will plus mode of this. So, this diverges. Therefore, this equality does not hold. In fact, if  $x_0$  is negative, you can choose the contour the other way; instead of closing it from the down, you can close this semicircle from up. And then, the other integration here from the semicircle on the upper half plane vanishes. So, now, you can see that, this is in fact equal to  $\frac{d^2 k}{(2\pi)^2} \frac{e^{-ik \cdot x_0}}{(k_0 + i\epsilon)^2 - \omega^2} = \frac{d^2 k}{(2\pi)^2 2\omega} \frac{d^2 k}{(2\pi)} e^{-ik \cdot x_0} \left( \frac{1}{k_0 + i\epsilon - \omega} - \frac{1}{k_0 + i\epsilon + \omega} \right)$  provided  $x_0$  is greater than 0.

Now, the reason I am considering this contour here is I can evaluate this integration using Cauchy's residue theorem here. Therefore, I have evaluated this integration when  $x_0$  is positive. So, what is the value of this integration when I use Cauchy's residue theorem? This in fact is  $2\pi i$  times... There are 2 poles; and then, you can just at the residues at both these poles,  $e$  to the power minus  $i\omega x_0$  minus  $e$  to the power  $i\omega x_0$ . This is what you get here – divided by  $2\pi$ . So, this I considered without this factor of  $i k \cdot x$  here. When I have  $i k \cdot x$ , I will have an additional  $e$  to the power  $i k \cdot x$ . So, I can substitute this in this integration here.

(Refer Slide Time: 44:19)

When I do that, what I get is... That is an  $i$  because there is a  $2\pi i$  in the residue theorem; and then,  $e$  to the power  $i k \cdot x$  times  $e$  to the power minus  $i\omega x_0$  minus  $e$  to the power  $i\omega x_0$  for  $x_0$  greater than 0. What is the value of this integration for  $x_0$  less than 0? We can again use the residue theorem. We can choose this contour

instead of the contour, where the semicircle is in the lower half plane. And, the contour – this – the integration on this contour will be equal to this integration if  $x_0$  is negative. But, this contour – the interior of this region does not include any pole here. So, the contour integration here is 0. Therefore, this integration here is 0 for  $x_0$  less than 0.

Now, this one you can rewrite it here. You can do a simple rewriting and then you can show that, this in fact is equal to the commutator of  $\phi$  of  $x$  with  $\phi$  of  $y$ . I will show this in a moment. So, this – you can consider this integration here. This is  $d^3k$  over  $(2\pi)^3$  times  $2\omega$ . Let us consider this for  $x_0$  greater than 0. What you can do is you can take this inside here and then this simply becomes  $e$  to the power minus  $i k \cdot x$  here; where,  $k_0$  is  $\omega$ . Whereas, in the second part, you can change this integration variable here from  $k$  to minus  $k$ . Nothing will change here, because these limits are such that this will remain invariant. And, here what you will get is  $\omega x_0$  minus  $k \cdot x$ ; which you can write as  $e$  to the power  $i k \cdot x$ ; all right? So, this entire thing here you can write it in a Lorentz invariant fashion; and, you can see that this is nothing but  $i$  times the commutator of  $\phi$  of  $x$  and  $\phi$  of  $y$ . So, the Green function what we have seen is that, the Green function of the Klein-Gordon operator is equal to the commutator of  $\phi$  of  $x$  times  $\phi$  of  $y$  provided  $x_0$  minus  $y_0$  is 0. And, this is 0 if  $x_0$  minus  $y_0$  is less than 0.

(Refer Slide Time: 48:05)

So, just to summarize, what we did is we have evaluated this and then we have shown that, this is equal to  $i$  times  $\theta$  of  $x_0$  minus  $y_0$  times the commutator of  $\phi$  of  $x$  and  $\phi$  of  $y$ ; all right?
