Lecture – 25
Electric field due to a line charge distribution

Hello. We have discussed the continuous charge density. Now, we will discuss some examples related to that.

(Refer Slide Time: 00:39)

Example

$\vec{r} = z \hat{z}$
 $\vec{r}' = x \hat{x}$
 $dl' = dx$

$\vec{r} = \vec{r} - \vec{r}' = z \hat{z} - x \hat{x}$
 $r = |\vec{r}| = \sqrt{z^2 + x^2}$
 $\hat{r} = \frac{\vec{r}}{r} = \frac{z \hat{z} - x \hat{x}}{\sqrt{z^2 + x^2}}$

$\vec{E} = \frac{1}{4\pi\epsilon_0} \int_{-L}^L \frac{\lambda}{z^2 + x^2} \frac{z \hat{z} - x \hat{x}}{\sqrt{z^2 + x^2}} dx$
 $= \frac{\lambda}{4\pi\epsilon_0} \left[z \hat{z} \int_{-L}^L \frac{1}{(z^2 + x^2)^{3/2}} dx - \hat{x} \int_{-L}^L \frac{x}{(z^2 + x^2)^{3/2}} dx \right]$

So, the first example that we will discuss is we will consider, we will try to find the electric field at a distance z above from the midpoint of a straight line segment of length $2L$ that carries a uniform line charge λ . What does that mean? We have a line here that carries uniform line charge λ and the length of this line segment is $2L$ twice of L . So, this

much length is twice of L and we will consider a point at a distance z above the midpoint of this line segment.

So, from this point, if we drop a normal on this line, then this part is L , this part is also L like this and this height of that point is z . So, let us consider a line element here dx . So, the position vector of our point of observation P can be given as \mathbf{r} ; where, \mathbf{r} is $z \hat{z}$ and the position vector of this little line element that we have here that can be given as \mathbf{r}' ; where, \mathbf{r}' is $x \hat{x}$ and dl' that is on the source, that is on the line charge distribution, a line element on this line charge distribution this can be given as dx clearly.

So, the distance between the distance vector between the point of observation and the source element is this much. This is curly \mathbf{r} that can be given as $\mathbf{r} - \mathbf{r}'$, the vector subtraction of this which is nothing but $z \hat{z} - x \hat{x}$. Given this, we can write the magnitude of this curly \mathbf{r} vector the distance vector that is the magnitude of the distance that is $\sqrt{z^2 + x^2}$ and the direction of this curly \mathbf{r} vector that is \mathbf{r} / r is $(z \hat{z} - x \hat{x}) / \sqrt{z^2 + x^2}$ of this.

So, the electric field for this charge distribution at the point of observation P would be given by $\frac{1}{4\pi\epsilon_0}$. We will have to integrate over dx from the range $-L$ to L assuming at the point where the normal is dropped the value of x equals 0 . We will have the charge density line charge density over $z^2 + x^2$ that is the distance squared, multi. Then, comes the unit vector along the distance that is $(z \hat{z} - x \hat{x}) / \sqrt{z^2 + x^2}$ times dx .

And this can be evaluated as $\frac{\lambda}{4\pi\epsilon_0} \int_{-L}^L \frac{z \hat{z} - x \hat{x}}{(z^2 + x^2)^{3/2}} dx$ minus we will have x out. We cannot take x out because x is a function of x we will have to keep it within the integral $\int_{-L}^L \frac{z \hat{z} - x \hat{x}}{(z^2 + x^2)^{3/2}} dx$. We need to evaluate this integral. How do we do that?

(Refer Slide Time: 06:40)

$$\begin{aligned} &= \frac{\lambda}{4\pi\epsilon_0} \left[\hat{z} \left(\frac{x}{z^2 \sqrt{z^2 + x^2}} \right) \Big|_{-L}^L - \hat{x} \left(-\frac{1}{\sqrt{z^2 + x^2}} \right) \Big|_{-L}^L \right] \\ &= \frac{1}{4\pi\epsilon_0} \frac{2\lambda L}{z \sqrt{z^2 + L^2}} \hat{z} \end{aligned}$$

If we try to evaluate this integral, we will end up getting lambda over 4 pi epsilon naught z z cap; x over z squared z squared plus x squared square root of this quantity minus L to L minus x cap minus 1 over z squared plus x squared square root. Here, also the limits say minus L to L.

So, we need to evaluate this and if we evaluate if we work out the algebra, we will find 1 over 4 pi epsilon naught 2 lambda L over z z square plus L square and the direction of this electric field would be z cap.
