**Lecture-48**  
**Recap, Poles/Zeros and Laplace Transform Notation**

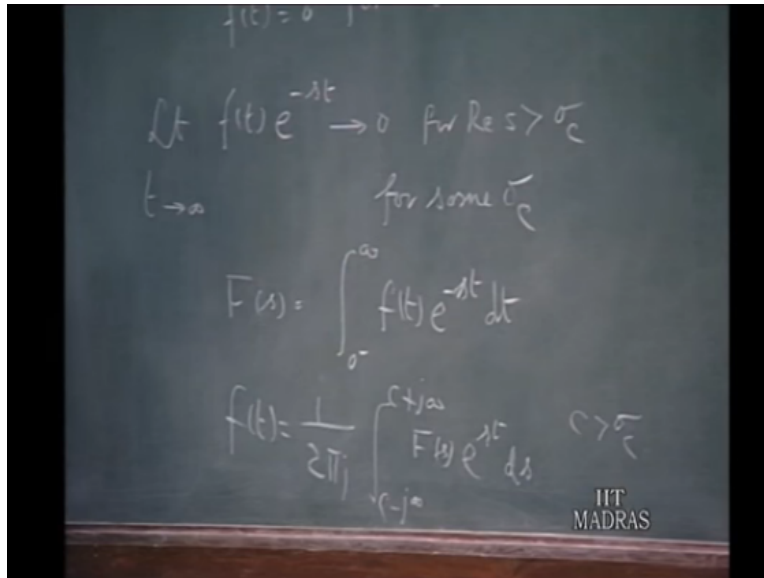

We had introduced ourselves to the concept of Laplace transformation of the function of time. In the last class and we had a look at the Laplace transforms of some important functions of time like the unity impulse function the unit step function and the 2 sinusoidal functions  $\cos \omega t$  and  $\sin \omega t$ . Let us, first recapitulate some of the important points that was discussed in the last class.

(Refer Slide Time: 00:53)

We are concerned with functions of time which are causal. So, the  $f$  of  $t$  which are concerned with are causal that is  $f$  of  $t$  is 0 for  $t$  less than 0. And further we said their exponential order; that means, limit as  $t$  goes infinite of  $f$  of  $t$   $e$  to the power of minus  $st$  close to 0 for real part of  $s$  greater than some number  $\sigma_c$  for some  $\sigma_c$  which is the function of  $f$  of  $t$ . So, if the function of time is the exponential order that is the  $t$  goes to infinite the  $e$  to the power of minus  $st$  is able to pull thus out the negligible proportion.

(Refer Slide Time: 02:21)

Then for such time functions we said we have a Laplace transformation  $f$  of  $s$ . Which is given by the integral sub 0 minus to infinite of  $f$  of  $t$   $e$  to the power of minus  $st$   $dt$ . That is; the forward Laplace transformation formula and the inverse Laplace transform is given by  $\frac{1}{2\pi j}$   $\int_{c-j\infty}^{c+j\infty} f$  of  $s$   $e$  to the power of  $st$   $ds$  this is the inverse Laplace transformation formula.

This contour of integration which extends from  $c$  minus  $j$  infinite to  $c$  plus  $j$  infinite is the vertical line in the region of the convergence of the Laplace transformation; that means,  $c$  must be larger than  $\sigma_c$ . And this contour of integration as i mentioned is referred to as the ground which contour. Now, as the result of this the Laplace transformation that we get is usually a rational function for the type of functions of time that we consider.

(Refer Slide Time: 03:43)

So, for the given  $f$  of  $t$  that we have we have an  $f$  of  $s$  which is the rational function. And this rational function by means, the ratio of 2 polynomial and this could be the 2 polynomial could be put in the form  $m$  is the numerator is factorized as  $s$  minus  $z_1$  minus  $z_2$  down the line  $z$  minus  $z_m$ . And the denominator likewise the factorized as  $s$  minus  $p_1$   $s$  minus  $p_2$   $s$  minus  $p_n$ , then the Laplace transformation epodes is defined by the values of the  $z$  value  $z_1, z_2, z_3, z_m$  and the values  $p_1$  up to  $p_n$  apart from the constant multiplied factor  $m$ .

So, this  $f$  of  $s$  can be represent in the complex plane by the location of the zeros of  $f$  of  $s$  and poles of  $f$  of  $s$ . So, zeros are normally marked by means of small circles. So, this may be 0 locations poles may be are marked by crosses. So, there may be a pole here pair a poles here extra. So, the pole in 0 locations are marked in the  $s$  plane.

So, the pole of 0 locations of  $f$  of  $s$  completely defined  $f$  of  $s$  expect for the multiplied factor  $m$ . And we also lot that as long as coefficients in the 2 polynomials are real then early complex pole is accompanists by its conjugate any complex 0 is accompanists by its conjugate and the absence of convergence is.

Sigma c the absence of convergence is larger than the maximum value of the real part of pi. So, whatever the pi you are having is the maximum value or the real part of pi i from 1 to n. So, that will be define the absence of convergence; that means, the region of convergence starts from the right most pole.

So, if this is the right most pole anything beyond that if there is in the conversions. So, the maximum value of the real part of the poles defines the reason of convergence. And we have seen this in the case of simple functions like the unit stuff function which as the sigma c as 0 of the e to the power of minus 2t where sigma is minus 2 and so an so for, as that is what we have seen earlier a few comments about.

(Refer Slide Time: 06:42)

The notation as i mentioned the Laplace transforms exists for unilateral Laplace transform that we are talking about exist only for causal time functions. So, if f of t by definition has the value for negative values of time as well, to make sure that we are talking about the truncated part of that function of t we normally write f of t to ut. To make sure that f of t the composite function is 0 for negative values of time.

Often instead of f of t ut we use simply f of t then there is no cause for confusion when there is no room for confusion. In other words example, suppose e to the power of

minus  $2t$  this is  $f$  of  $t$  that you are talking that you can't find Laplace transform such a function. We have to find the Laplace transform and  $e$  to the power of minus  $2t$  times  $ut$ .

So, when you are got  $1$  over  $x$  plus  $2$  the inverse Laplace transform of that  $e$  to the power of minus  $2t$  times  $ut$ . Instead of that we write  $e$  to the power of minus  $2t$  itself, with the understanding that we are talking about  $e$  to the power of minus  $2t$  valid for  $t$  greater than or equal to  $0$ . So, as long as we understand that whatever time function we are having is valid only for  $t$  greater than or equal to  $0$  and it is  $0$  for negative values for time.

Instead for  $e$  to the power of minus  $2t$  times  $ut$  we offer by  $e$  to the power of minus  $2t$  to save or write. Another point is suppose we have a some constant. Laplace transform of some constant  $k$  again by definition by constant  $k$  exists for all values of time, but in the context of Laplace time form. We assume the distance function is the value  $k$  starting from  $t$  equal  $0$  minus. Because we can take only functions which are  $0$  for negative values of time in the Laplace transformation consideration.

Therefore, even if you take the going to Laplace transformation constant. We regard that constant that will have the function will have the value  $k$  starting from  $t$  equal to  $0$  minus and  $0$  for values of  $t$  less than this. So, when we are talking about the Laplace transform the constant. We treat this as Laplace transform of  $k$  times  $ut$  at say this is  $k$  apart  $s$ .

So, we do not sometimes exhibits specifically this  $u$  of  $t$  which understood just to say, a right. Another feature of common notation is you recall that I said  $\cos \omega t$  has Laplace transformation  $s$  over  $s^2$  plus  $\omega^2$ . We have taken a particular angular frequency  $\omega$  and truncate it at  $t$  equals for negative values of time and arrive get this Laplace transformation.

Now,  $s$  is equal to  $\sigma$  plus  $j\omega$ . The imaginary part of  $s$  is also given the simple  $\omega$  it is a running variable and to distinguish that running variable  $\omega$  with this

omega. So, we have given as a special simple as a omega not. But in our manipulation we very rarely decompose  $s$  into  $\sigma + j\omega$  looks at the imaginary part of  $s$ .

So, where there is no confusion we even write simply  $\cos \omega t$  having a Laplace transform. As  $s^2 + \omega^2$  as this is return in this manner in this notation we understand that this omega is not to be confused with the imaginary part of the  $s$ . This is the omega a particular value of omega associate a trigonometric function this should not be confused with the imaginary component of  $s$ .

And secondly, as we mentioned earlier actually we are talking about  $\cos \omega t u(t)$ . But this additional function  $u(t)$  is often dropped. Assuming that, we are talking about a function which has this functional notation only  $t \geq 0$  plus onwards  $t < 0$  minus onwards. So, often instead of writing like this we simply said  $\cos \omega t$  is the Laplace transform  $s$  over  $s^2 + \omega^2$ .

These are minor deviations in the notation we often find to simplify the writing of the various expressions this type of simplification is distorted. But basically, we must note that whatever function we are talking about is assumed to be 0 for values of  $t < 0$  minus.
