Lecture-59A
Inverse Laplace Transform and Contour Integration

Today at the method of finding out the inverse Laplace transformation, using the partial fraction expansion.

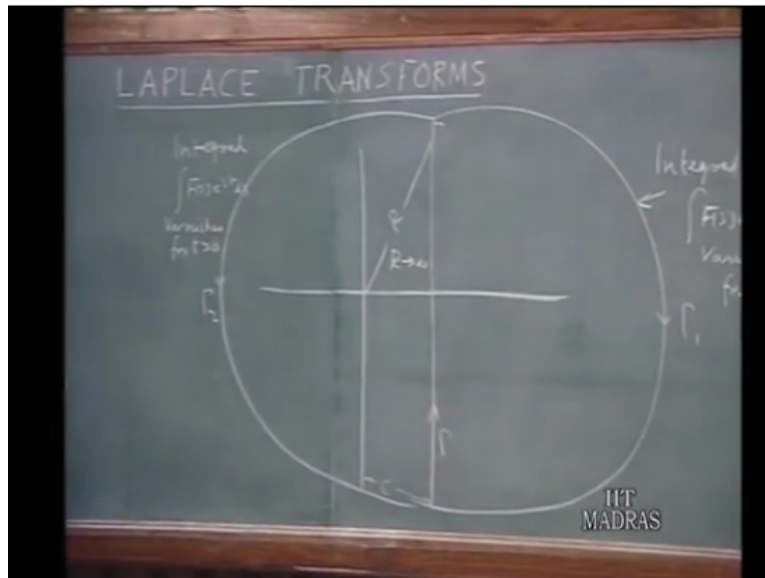

(Refer Slide Time: 00:31)

The image shows a handwritten equation on a chalkboard. At the top, the words "Contour Integration" are written and underlined. Below this, the equation is written as $f(t) = \frac{1}{2\pi j} \int_{c-j\infty}^{c+j\infty} F(s) e^{st} ds$. The integration path is a vertical line in the complex s-plane, with the upper limit labeled $c+j\infty$ and the lower limit labeled $c-j\infty$. In the bottom right corner of the chalkboard, the text "IIT MADRAS" is visible.

There is another method which is the contour integration, which is more fundamental, and which terms from the very definition of the inverse Laplace transformation. You recall the inverse Laplace transformation $f(t)$ is $\frac{1}{2\pi j} \int_{c-j\infty}^{c+j\infty} F(s) e^{st} ds$.

(Refer Slide Time: 01:05)

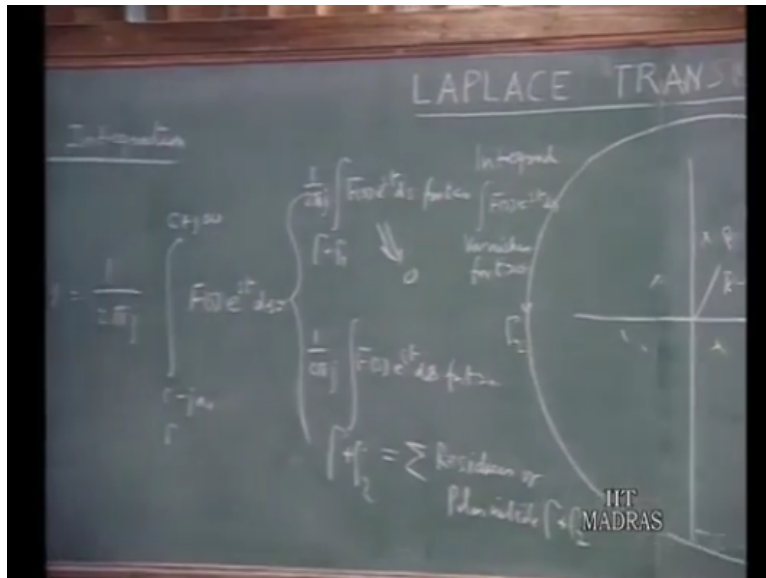

So, in the complex plane, you take the integration contour like this $c - j\infty$, all the way down to $c + j\infty$. Let me say this contour is γ . So, this integration is a long term, this. Now it is easy to evaluate the integral along a close contour in a complex plane, because from the theory of residues. Once you have integration over a close contour that is equal to $2\pi j$ times, the residues of the poles inside the contour of the complex variable theory.

So, what one does is, this to close this by means of, too large semicircles where r tends to infinity. Let me call this γ_1 , γ_2 . It turns out that if you have this integral evaluated around this contour for $t < 0$ it vanishes. So, integral $f(s)e^{st}$ vanishes along this contour for $t < 0$. On the other hand if you take it along this contour γ_2 , this integral $f(s)e^{st} ds$ vanishes for $t > 0$.

So, since we have, we want to really evaluate this integral along this contour, from this point to this point. But nothing is lost if you have to this contour, this particular large semicircle for $t < 0$, and this large semicircle for $t > 0$.

(Refer Slide Time: 03:19)

So, in other words I can say, this is equal to $\frac{1}{2\pi j} \int_{\gamma} F(s)e^{st} ds$ evaluate the contour cross contour $\gamma + j\omega$ of $f(s)e^{st}$ for $t < 0$, because of all I made in to that, a quantity which is equal to 0, and this is equal to $\frac{1}{2\pi j} \int_{\gamma} F(s)e^{st} ds$ integral along this close contour for $t > 0$, and it turns out that. As far as this contour integration is concerned, there are no poles inside as long, because all the poles will be here.

Therefore, since this close contour does not include any poles this transfer to be 0, and as for this is concerned. This will be equal to the sum of the residues of poles inside the close contour 2. So, whatever poles you are having here, you have take the residues of the poles that will be equal to $f(t)$ for $t > 0$; this is for $t > 0$, this is for $t < 0$. So, in the inverse Laplace transform you will get $f(t)$ identically 0 of $t < 0$, because of this, and for $t > 0$, it is equal to sum of the residues of the poles inside this.

Our discussion here is lesser to be cursory, because this is not the method that we used for normally evaluate of the inverse Laplace transformation. Just giving this to you the shape of completeness and the partial fraction expansion is. So, much simpler and that takes care of most of our needs.

We do not really have to the contour integration. But, because this is basic one, and this will have to be resorted to, for special types of functions which we may not know the inverse Laplace transform simply, so I included this. So, we will not pursue this topic, just mention the contour integration is alternative method to finding out the Laplace transformation.
